Chapter 3

Data Structure Documentation

3.1 AllGlobals Struct Reference

```
#include <structs.h>
```

Collaboration diagram for AllGlobals:

Public Member Functions

- **PADPOSITION** (0, 0, 0, 0, sizeof(struct P_const)+sizeof(struct T_const)+sizeof(struct X_const))

Data Fields

- struct M_const M
- struct C_const C
- struct S_const S
- struct R_const R
- struct N_const N
- struct O_const O
- struct P_const P
- struct T_const T
- struct X_const X

3.1.1 Detailed Description

Without pthreads (FORM) the ALLGLOBALS struct has all the global variables

Definition at line 2457 of file structs.h.

3.1.2 Field Documentation

3.1.2.1 M

```
struct M_const AllGlobals::M
```

Definition at line 2458 of file structs.h.

3.1.2.2 C

```
struct C_const AllGlobals::C
```

Definition at line 2459 of file structs.h.

3.1.2.3 S

```
struct S_const AllGlobals::S
```

Definition at line 2460 of file structs.h.

3.1.2.4 R

```
struct R_const AllGlobals::R
```

Definition at line 2461 of file structs.h.

3.1.2.5 N

```
struct N_const AllGlobals::N
```

Definition at line 2462 of file structs.h.

3.1.2.6 O

```
struct O_const AllGlobals::O
```

Definition at line 2463 of file structs.h.

3.1.2.7 P

```
struct P_const AllGlobals::P
```

Definition at line 2464 of file structs.h.

3.1.2.8 T

```
struct T_const AllGlobals::T
```

Definition at line 2465 of file structs.h.

3.1.2.9 X

```
struct X_const AllGlobals::X
```

Definition at line 2466 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.2 ARGBUFFER Struct Reference

Collaboration diagram for ARGBUFFER:

Data Fields

- WORD * buffer
- DOLLARS dollar
- LONG size
- int type
- int dummy

3.2.1 Detailed Description

Definition at line 601 of file ratio.c.

3.2.2 Field Documentation

3.2.2.1 buffer

```
WORD* ARGBUFFER::buffer
```

Definition at line 602 of file ratio.c.

3.2.2.2 dollar

```
DOLLARS ARGBUFFER::dollar
```

Definition at line 603 of file ratio.c.

3.2.2.3 size

```
LONG ARGBUFFER::size
```

Definition at line 604 of file ratio.c.

3.2.2.4 type

```
int ARGBUFFER::type
```

Definition at line 605 of file ratio.c.

3.2.2.5 dummy

```
int ARGBUFFER::dummy
```

Definition at line 606 of file ratio.c.

The documentation for this struct was generated from the following file:

- ratio.c

3.3 bit_field Struct Reference

```
#include <structs.h>
```

Data Fields

- UBYTE bit_0: 1
- UBYTE bit_1: 1
- UBYTE bit_2: 1
- UBYTE bit_3: 1
- UBYTE bit_4: 1
- UBYTE bit_5: 1
- UBYTE bit_6: 1
- UBYTE bit_7: 1

3.3.1 Detailed Description

The struct bit_field is used by set_in, set_set, set_del and set_sub. They in turn are used in pre.c to toggle bits that indicate whether a character can be used as a separator of function arguments. This facility is used in the communication with external channels.

Definition at line 878 of file structs.h.

3.3.2 Field Documentation

3.3.2.1 bit_0

```
UBYTE bit_field::bit_0
```

Definition at line 879 of file structs.h.

3.3.2.2 bit_1

```
UBYTE bit_field::bit_1
```

Definition at line 880 of file structs.h.

3.3.2.3 bit_2

```
UBYTE bit_field::bit_2
```

Definition at line 881 of file structs.h.

3.3.2.4 bit_3

```
UBYTE bit_field::bit_3
```

Definition at line 882 of file structs.h.

3.3.2.5 bit_4

```
UBYTE bit_field::bit_4
```

3.7.1 Detailed Description

The C_const struct is part of the global data and resides in the ALLGLOBALS struct A under the name #C. We see it used with the macro AC as in AC.exprnames. It contains variables that involve the compiler and objects set during compilation.

Definition at line 1613 of file structs.h.

3.7.2 Field Documentation

3.7.2.1 separators

```
set_of_char C_const::separators
```

Separators in #call and #do

Definition at line 1614 of file structs.h.

3.7.2.2 StoreFileSize

```
POSITION C_const::StoreFileSize
```

Definition at line 1615 of file structs.h.

3.7.2.3 dollarnames

```
NAMETREE* C_const::dollarnames
```

[D] Names of dollar variables

Definition at line 1616 of file structs.h.

3.7.2.4 exprnames

```
NAMETREE* C_const::exprnames
```

[D] Names of expressions

Definition at line 1617 of file structs.h.

3.7.2.5 varnames

```
NAMETREE* C_const::varnames
```

[D] Names of regular variables

Definition at line 1618 of file structs.h.

3.7.2.6 ChannelList

```
LIST C_const::ChannelList
```

Used for the #write statement. Contains CHANNEL

Definition at line 1619 of file structs.h.

3.7.2.7 DubiousList

```
LIST C_const::DubiousList
```

List of dubious variables. Contains DUBIOUSV. If not empty -> no execution

Definition at line 1621 of file structs.h.

3.7.2.8 FunctionList

```
LIST C_const::FunctionList
```

List of functions and properties. Contains FUNCTIONS

Definition at line 1623 of file structs.h.

3.7.2.9 ExpressionList

```
LIST C_const::ExpressionList
```

List of expressions, locations etc.

Definition at line 1624 of file structs.h.

3.7.2.10 IndexList

```
LIST C_const::IndexList
```

List of indices

Definition at line 1625 of file structs.h.

3.7.2.11 SetElementList

```
LIST C_const::SetElementList
```

List of all elements of all sets

Definition at line 1626 of file structs.h.

3.7.2.12 SetList

```
LIST C_const::SetList
```

List of the sets

Definition at line 1627 of file structs.h.

3.7.2.13 SymbolList

```
LIST C_const::SymbolList
```

List of the symbols and their properties

Definition at line 1628 of file structs.h.

3.7.2.14 VectorList

```
LIST C_const::VectorList
```

List of the vectors

Definition at line 1629 of file structs.h.

3.7.2.15 PotModDolList

```
LIST C_const::PotModDolList
```

Potentially changed dollars

Definition at line 1630 of file structs.h.

3.7.2.16 ModOptDolList

```
LIST C_const::ModOptDolList
```

Module Option Dollars list

Definition at line 1631 of file structs.h.

3.7.2.17 TableBaseList

```
LIST C_const::TableBaseList
```

TableBase list

Definition at line 1632 of file structs.h.

3.7.2.18 cbufList

```
LIST C_const::cbufList
```

List of compiler buffers

Definition at line 1636 of file structs.h.

3.7.2.19 AutoSymbolList

```
LIST C_const::AutoSymbolList
```

Definition at line 1640 of file structs.h.

3.7.2.20 AutoIndexList

```
LIST C_const::AutoIndexList
```

Definition at line 1641 of file structs.h.

3.7.2.21 AutoVectorList

```
LIST C_const::AutoVectorList
```

Definition at line 1642 of file structs.h.

3.7.2.22 AutoFunctionList

```
LIST C_const::AutoFunctionList
```

Definition at line 1643 of file structs.h.

3.7.2.23 autonames

```
NAMETREE* C_const::autonames
```

[D] Names in autodeclare

Definition at line 1644 of file structs.h.

3.7.2.24 Symbols

```
LIST* C_const::Symbols
```

Definition at line 1646 of file structs.h.

3.7.2.25 Indices

```
LIST* C_const::Indices
```

Definition at line 1648 of file structs.h.

3.7.2.26 Vectors

```
LIST* C_const::Vectors
```

Definition at line 1649 of file structs.h.

3.7.2.27 Functions

```
LIST* C_const::Functions
```

Definition at line 1650 of file structs.h.

3.7.2.28 activenames

```
NAMETREE** C_const::activenames
```

Definition at line 1651 of file structs.h.

3.7.2.29 Streams

```
STREAM* C_const::Streams
```

(C) Pointer for AutoDeclare statement. Points either to varnames or autonames. [D] The input streams.

Definition at line 1653 of file structs.h.

3.7.2.30 CurrentStream

```
STREAM* C_const::CurrentStream
```

(C) The current input stream. Streams are: do loop, file, prevariable. points into Streams memory.

Definition at line 1654 of file structs.h.

3.7.2.31 SwitchArray

```
SWITCH* C_const::SwitchArray
```

Definition at line 1656 of file structs.h.

3.7.2.32 SwitchHeap

```
WORD* C_const::SwitchHeap
```

Definition at line 1657 of file structs.h.

3.7.2.33 termstack

```
LONG* C_const::termstack
```

[D] Last term statement {offset}

Definition at line 1658 of file structs.h.

3.7.2.34 termsortstack

```
LONG* C_const::termsortstack
```

[D] Last sort statement {offset}

Definition at line 1659 of file structs.h.

3.7.2.35 cmod

```
UWORD* C_const::cmod
```

[D] Local setting of modulus. Pointer to value.

Definition at line 1660 of file structs.h.

3.7.2.36 powmod

```
UWORD* C_const::powmod
```

Local setting printing as powers. Points into cmod memory

Definition at line 1661 of file structs.h.

3.7.2.37 modpowers

```
UWORD* C_const::modpowers
```

[D] The conversion table for mod->powers.

Definition at line 1662 of file structs.h.

3.7.2.38 halfmod

```
UWORD* C_const::halfmod
```

Definition at line 1663 of file structs.h.

3.7.2.39 ProtoType

```
WORD* C_const::ProtoType
```

Definition at line 1664 of file structs.h.

3.7.2.40 WildC

```
WORD* C_const::WildC
```

Definition at line 1665 of file structs.h.

3.7.2.41 IfHeap

```
LONG* C_const::IfHeap
```

[D] Keeps track of where to go in if

Definition at line 1666 of file structs.h.

3.7.2.42 IfCount

```
LONG* C_const::IfCount
```

[D] Keeps track of where to go in if

Definition at line 1667 of file structs.h.

3.7.2.43 IfStack

```
LONG* C_const::IfStack
```

Keeps track of where to go in if. Points into IfHeap-memory

Definition at line 1668 of file structs.h.

3.7.2.44 iBuffer

```
UBYTE* C_const::iBuffer
```

[D] Compiler input buffer

Definition at line 1669 of file structs.h.

3.7.2.45 iPointer

```
UBYTE* C_const::iPointer
```

Running pointer in the compiler input buffer

Definition at line 1670 of file structs.h.

3.7.2.46 iStop

```
UBYTE* C_const::iStop
```

Top of iBuffer

Definition at line 1671 of file structs.h.

3.7.2.47 LabelNames

```
UBYTE** C_const::LabelNames
```

[D] List of names in label statements

Definition at line 1672 of file structs.h.

3.7.2.48 FixIndices

```
WORD* C_const::FixIndices
```

[D] Buffer of fixed indices

Definition at line 1673 of file structs.h.

3.7.2.49 termsumcheck

```
WORD* C_const::termsumcheck
```

[D] Checking of nesting

Definition at line 1674 of file structs.h.

3.7.2.50 WildcardNames

```
UBYTE* C_const::WildcardNames
```

[D] Names of ?a variables

Definition at line 1675 of file structs.h.

3.7.2.51 Labels

```
int* C_const::Labels
```

Label information for during run. Pointer into LabelNames memory.

Definition at line 1676 of file structs.h.

3.7.2.52 tokens

```
SBYTE* C_const::tokens
```

[D] Array with tokens for tokenizer

Definition at line 1677 of file structs.h.

3.7.2.53 toptokens

```
SBYTE* C_const::toptokens
```

Top of tokens

Definition at line 1678 of file structs.h.

3.7.2.54 endoftokens

```
SBYTE* C_const::endoftokens
```

End of the actual tokens

Definition at line 1679 of file structs.h.

3.7.2.55 tokenarglevel

```
WORD* C_const::tokenarglevel
```

[D] Keeps track of function arguments

Definition at line 1680 of file structs.h.

3.7.2.56 modinverses

```
UWORD* C_const::modinverses
```

Definition at line 1681 of file structs.h.

3.7.2.57 Fortran90Kind

```
UBYTE* C_const::Fortran90Kind
```

Definition at line 1682 of file structs.h.

3.7.2.58 MultiBracketBuf

```
WORD** C_const::MultiBracketBuf
```

Definition at line 1683 of file structs.h.

3.7.2.59 extrasym

```
UBYTE* C_const::extrasym
```

Definition at line 1684 of file structs.h.

3.7.2.60 doloopstack

```
WORD* C_const::doloopstack
```

Definition at line 1685 of file structs.h.

3.7.2.61 doloopnest

```
WORD* C_const::doloopnest
```

Definition at line 1686 of file structs.h.

3.7.2.62 CheckpointRunAfter

```
char* C_const::CheckpointRunAfter
```

[D] Filename of script to be executed *before* creating the snapshot. =0 if no script shall be executed.

Definition at line 1687 of file structs.h.

3.7.2.63 CheckpointRunBefore

```
char* C_const::CheckpointRunBefore
```

[D] Filename of script to be executed *after* having created the snapshot. =0 if no script shall be executed.

Definition at line 1689 of file structs.h.

3.7.2.64 IfSumCheck

```
WORD* C_const::IfSumCheck
```

[D] Keeps track of if-nesting

Definition at line 1691 of file structs.h.

3.7.2.65 CommuteInSet

```
WORD* C_const::CommuteInSet
```

Definition at line 1692 of file structs.h.

3.7.2.66 TestValue

```
UBYTE* C_const::TestValue
```

Definition at line 1693 of file structs.h.

3.7.2.67 argstack

```
LONG C_const::argstack[MAXNEST]
```

Definition at line 1701 of file structs.h.

3.7.2.68 insidestack

```
LONG C_const::insidestack[MAXNEST]
```

Definition at line 1702 of file structs.h.

3.7.2.69 inexprstack

```

3.7.2.72 ProcessBucketSize

```
LONG C_const::ProcessBucketSize
```

Definition at line 1707 of file structs.h.

3.7.2.73 mProcessBucketSize

```
LONG C_const::mProcessBucketSize
```

Definition at line 1708 of file structs.h.

3.7.2.74 CModule

```
LONG C_const::CModule
```

Definition at line 1709 of file structs.h.

3.7.2.75 ThreadBucketSize

```
LONG C_const::ThreadBucketSize
```

Definition at line 1710 of file structs.h.

3.7.2.76 CheckpointStamp

```
LONG C_const::CheckpointStamp
```

Timestamp of the last created snapshot (set to Timer(0)).

Definition at line 1711 of file structs.h.

3.7.2.77 CheckpointInterval

```
LONG C_const::CheckpointInterval
```

Time interval in milliseconds for snapshots. =0 if snapshots shall be created at the end of *every* module.

Definition at line 1712 of file structs.h.

3.7.2.78 cbufnum

```
int C_const::cbufnum
```

Current compiler buffer

Definition at line 1714 of file structs.h.

3.7.2.79 AutoDeclareFlag

```
int C_const::AutoDeclareFlag
```

Definition at line 1715 of file structs.h.

3.7.2.80 NoShowInput

```
int C_const::NoShowInput
```

(C) Mode of looking for names. Set to NOAUTO (=0) or WITHAUTO (=2), cf. AutoDeclare statement

Definition at line 1717 of file structs.h.

3.7.2.81 ShortStats

```
int C_const::ShortStats

- int maxrhs
- int mnumlhs
- int mnumrhs
- int numtree
- int rootnum
- int MaxTreeSize

3.8.1 Detailed Description

The CBUF struct is used by the compiler. It is a compiler buffer of which since version 3.0 there can be many.

Definition at line 938 of file structs.h.

3.8.2 Field Documentation

3.8.2.1 Buffer

```
WORD* CbUf::Buffer
```

[D] Size in BufferSize

Definition at line 939 of file structs.h.

Referenced by CleanupArgCache(), clearcbuf(), DoubleCbuffer(), finishcbuf(), inicbufs(), PF_BroadcastCBuf(), and Processor().

3.8.2.2 Top

```
WORD* CbUf::Top
```

pointer to the end of the Buffer memory

Definition at line 940 of file structs.h.

Referenced by AddNtoC(), AddNtoL(), DoubleCbuffer(), finishcbuf(), inicbufs(), PF_BroadcastCBuf(), and TestSub().

3.8.2.3 Pointer

```
WORD* CbUf::Pointer
```

pointer into the Buffer memory

Definition at line 941 of file structs.h.

Referenced by AddLHS(), AddNtoC(), AddNtoL(), AddRHS(), CleanupArgCache(), clearcbuf(), DoubleCbuffer(), finishcbuf(), Generator(), inicbufs(), PF_BroadcastCBuf(), Processor(), and TestSub().

3.8.2.4 lhs

```
WORD** CbUf::lhs
```

[D] Size in maxlhs. list of pointers into Buffer.

Definition at line 942 of file structs.h.

Referenced by AddLHS(), DoubleCbuffer(), finishcbuf(), Generator(), inicbufs(), PF_BroadcastCBuf(), Processor(), and TestMatch().

3.8.2.5 rhs

```
WORD** CbUf::rhs
```

[D] Size in maxrhs. list of pointers into Buffer.

Definition at line 943 of file structs.h.

Referenced by AddRHS(), CleanupArgCache(), clearcbuf(), DoubleCbuffer(), finishcbuf(), Generator(), inicbufs(), IniFbuffer(), PF_BroadcastCBuf(), Processor(), and TestSub().

3.8.2.6 CanCommu

```
LONG* CbUf::CanCommu
```

points into rhs memory behind WORD∗ area.

Definition at line 944 of file structs.h.

Referenced by AddRHS(), finishcbuf(), inicbufs(), IniFbuffer(), PF_BroadcastCBuf(), and TestSub().

3.8.2.7 NumTerms

```
LONG* CbUf::NumTerms
```

points into rhs memory behind CanCommu area

Definition at line 945 of file structs.h.

Referenced by AddRHS(), finishcbuf(), inicbufs(), IniFbuffer(), and PF_BroadcastCBuf().

3.8.2.8 numdum

```
WORD* CbUf::numdum
```

points into rhs memory behind NumTerms

Definition at line 946 of file structs.h.

Referenced by AddRHS(), inicbufs(), IniFbuffer(), and PF_BroadcastCBuf().

3.8.2.9 dimension

```
WORD* CbUf::dimension
```

points into rhs memory behind numdum

Definition at line 947 of file structs.h.

Referenced by AddRHS(), inicbufs(), IniFbuffer(), and PF_BroadcastCBuf().

3.8.2.10 boomlijst

```
COMPTREE* CbUf::boomlijst
```

[D] Number elements in MaxTreeSize

Definition at line 948 of file structs.h.

Referenced by CleanupArgCache(), clearcbuf(), finishcbuf(), inicbufs(), IniFbuffer(), and PF_BroadcastCBuf().

3.8.2.11 BufferSize

```
LONG CbUf::BufferSize
```

Number of allocated WORD's in Buffer

Definition at line 949 of file structs.h.

Referenced by DoubleCbuffer(), finishcbuf(), inicbufs(), and PF_BroadcastCBuf().

3.8.2.12 numlhs

```
int CbUf::numlhs
```

Definition at line 950 of file structs.h.

3.8.2.13 numrhs

```
int CbUf::numrhs
```

Definition at line 951 of file structs.h.

3.8.2.14 maxlhs

```
int CbUf::maxlhs
```

Definition at line 952 of file structs.h.

3.8.2.15 maxrhs

```
int CbUf::maxrhs
```

Definition at line 953 of file structs.h.

3.8.2.16 mnumlhs

```
int CbUf::mnumlhs
```

Definition at line 954 of file structs.h.

3.8.2.17 mnumrhs

```
int CbUf::mnumrhs
```

Definition at line 955 of file structs.h.

3.8.2.18 numtree

```
int CbUf::numtree
```

Definition at line 956 of file structs.h.

3.8.2.19 rootnum

```
int CbUf::rootnum
```

Definition at line 957 of file structs.h.

3.8.2.20 MaxTreeSize

```
int CbUf::MaxTreeSize
```

Definition at line 958 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.9 ChAnNeL Struct Reference

```
#include <structs.h>
```

Data Fields

- char * name
- int handle

3.9.1 Detailed Description

When we read input from text files we have to remember not only their handle but also their name. This is needed for error messages. Hence we call such a file a channel and reserve a struct of type CHANNEL to allow to lay this link.

Definition at line 969 of file structs.h.

3.9.2 Field Documentation

3.9.2.1 name

```
char* ChAnNeL::name
```

[D] Name of the channel

Definition at line 970 of file structs.h.

3.9.2.2 handle

```
int ChAnNeL::handle
```

File handle

Definition at line 971 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.10 COST Struct Reference

Data Fields

- LONG add
- LONG mul
- LONG div
- LONG pow

3.10.1 Detailed Description

Definition at line 1241 of file structs.h.

3.10.2 Field Documentation

3.10.2.1 add

`LONG COST::add`

Definition at line 1242 of file structs.h.

3.10.2.2 mul

`LONG COST::mul`

Definition at line 1243 of file structs.h.

3.10.2.3 div

`LONG COST::div`

Definition at line 1244 of file structs.h.

3.10.2.4 pow

`LONG COST::pow`

Definition at line 1245 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.11 dbase Struct Reference

Collaboration diagram for dbase:

Data Fields

- INIINFO info
- MLONG mode

- WORD * PObuffer
- WORD * POstop
- WORD * POfill
- WORD * POfull
- char * name
- ULONG numblocks
- ULONG inbuffer
- LONG POsize
- int handle
- int active

3.25.1 Detailed Description

The type FILEHANDLE is the struct that controls all relevant information of a file, whether it is open or not. The file may even not yet exist. There is a system of caches (PObuffer) and as long as the information to be written still fits inside the cache the file may never be created. There are variables that can store information about different types of files, like scratch files or sort files. Depending on what is available in the system we may also have information about gzip compression (currently sort file only) or locks (TFORM).

Definition at line 633 of file structs.h.

3.27 FiLeInDeX Struct Reference

```
#include <structs.h>
```

Collaboration diagram for FiLeInDeX:

Data Fields

- POSITION next
- POSITION number
- INDEXENTRY expression [INFILEINDEX]
- SBYTE empty [EMPTYININDEX]

3.27.1 Detailed Description

Defines the structure of a file index in store-files and save-files.

It contains several entries (see struct InDeXeNtRy) up to a maximum of INFILEINDEX.

The variable number has been made of type POSITION to avoid padding problems with some types of computers/↩ OS and keep system independence of the .sav files.

This struct is always 512 bytes long.

Definition at line 137 of file structs.h.

3.27.2 Field Documentation

3.27.2.1 next

```
POSITION FiLeInDeX::next
```

Position of next FILEINDEX if any

Definition at line 138 of file structs.h.

Referenced by ReadSaveIndex().

3.27.2.2 number

```
POSITION FiLeInDeX::number
```

Number of used entries in this index

Definition at line 139 of file structs.h.

Referenced by ReadSaveIndex().

3.27.2.3 expression

```
INDEXENTRY FiLeInDeX::expression[INFILEINDEX]
```

File index entries

Definition at line 140 of file structs.h.

3.27.2.4 empty

```
SBYTE FiLeInDeX::empty[EMPTYININDEX]
```

Padding to 512 bytes

Definition at line 141 of file structs.h.

The documentation for this struct was generated from the following file:

3.28 FixedGlobals Struct Reference

```
#include <structs.h>
```

Data Fields

- WCN Operation [8]
- WCN2 OperaFind [6]
- char * VarType [10]
- char * ExprStat [21]
- char * FunNam [2]
- char * swmes [3]
- char * fname
- char * fname2
- UBYTE * s_one
- WORD fnamebase
- WORD fname2base
- UINT cTable [256]

3.28.1 Detailed Description

The FIXEDGLOBALS struct is an anachronism. It started as the struct with global variables that needed initialization. It contains the elements Operation and OperaFind which define a very early way of automatically jumping to the proper operation. We find the results of it in parts of the file opera.c Later operations were treated differently in a more transparent way. We never changed the existing code. The most important part is currently the cTable which is used intensively in the compiler.

Definition at line 2509 of file structs.h.

- WORD * location
- int numargs
- int numfunnies
- int numwildcards
- int symmet
- int tensor
- int commute

3.30.1 Detailed Description

The struct FUN_INFO is used for information about functions in the file smart.c which is supposed to intelligently look for patterns in complicated wildcard situations involving symmetric functions.

Definition at line 606 of file structs.h.

3.30.2 Field Documentation

3.30.2.1 location

```
WORD* FUN_INFO::location
```

Definition at line 607 of file structs.h.

3.30.2.2 numargs

```
int FUN_INFO::numargs
```

Definition at line 608 of file structs.h.

3.30.2.3 numfunnies

```
int FUN_INFO::numfunnies
```

Definition at line 609 of file structs.h.

3.30.2.4 numwildcards

```
int FUN_INFO::numwildcards
```

Definition at line 610 of file structs.h.

3.30.2.5 symmet

```
int FUN_INFO::symmet
```

Definition at line 611 of file structs.h.

3.30.2.6 tensor

```
int FUN_INFO::tensor
```

Definition at line 612 of file structs.h.

3.30.2.7 commute

```
int FUN_INFO::commute
```

Definition at line 613 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.31 FuNcTiOn Struct Reference

```
#include <structs.h>
```

Collaboration diagram for FuNcTiOn:

Data Fields

- TABLES tabl
- LONG symminfo
- LONG name
- WORD commute
- WORD complex
- WORD number
- WORD flags
- WORD spec
- WORD symmetric
- WORD node
- WORD namesize
- WORD dimension
- WORD maxnumargs
- WORD minnumargs

3.31.1 Detailed Description

Contains all information about a function. Also used for tables. It is used in the LIST elements of AC.

Definition at line 475 of file structs.h.

3.31.2 Field Documentation

3.31.2.1 tabl

`TABLES FuNcTiOn::tabl`

Used if redefined as table. != 0 if function is a table

Definition at line 476 of file structs.h.

3.31.2.2 symminfo

`LONG FuNcTiOn::symminfo`

Info regarding symm properties offset in buffer

Definition at line 477 of file structs.h.

3.31.2.3 name

`LONG FuNcTiOn::name`

Location in namebuffer of NAMETREE

Definition at line 478 of file structs.h.

Referenced by StartVariables().

3.31.2.4 commute

`WORD FuNcTiOn::commute`

Commutation properties

Definition at line 479 of file structs.h.

3.31.2.5 complex

`WORD FuNcTiOn::complex`

Properties under complex conjugation

Definition at line 480 of file structs.h.

3.31.2.6 number

```
WORD FuNcTiOn::number
```

Number when stored in file

Definition at line 481 of file structs.h.

Referenced by ReadSaveIndex().

3.31.2.7 flags

```
WORD FuNcTiOn::flags
```

Used to indicate usage when storing

Definition at line 482 of file structs.h.

3.31.2.8 spec

```
WORD FuNcTiOn::spec
```

Regular, Tensor, etc. See FunSpecs.

Definition at line 483 of file structs.h.

Referenced by ReadSaveVariables().

3.31.2.9 symmetric

```
WORD FuNcTiOn::symmetric
```

0 if symmetric properties

Definition at line 484 of file structs.h.

Referenced by StartVariables().

3.31.2.10 node

```
WORD FuNcTiOn::node
```

Location in namenode of NAMETREE

Definition at line 485 of file structs.h.

3.31.2.11 namesize

```
WORD FuNcTiOn::namesize
```

Length of the name

Definition at line 486 of file structs.h.

3.31.2.12 dimension

```
WORD FuNcTiOn::dimension
```

Definition at line 487 of file structs.h.

3.31.2.13 maxnumargs

```
WORD FuNcTiOn::maxnumargs
```

Definition at line 488 of file structs.h.

3.31.2.14 minnumargs

```
WORD FuNcTiOn::minnumargs
```

Definition at line 489 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.32 gcd_heuristic_failed Class Reference

3.32.1 Detailed Description

Definition at line 33 of file polygcd.h.

The documentation for this class was generated from the following file:

- polygcd.h

3.33 HANDLERS Struct Reference

```
#include <structs.h>
```

Data Fields

- WORD newlogonly
- WORD newhandle
- WORD oldhandle
- WORD oldlogonly
- WORD oldprinttype
- WORD oldsilent

3.33.1 Detailed Description

The struct HANDLERS is used in the communication with external channels.

Definition at line 915 of file structs.h.

3.33.2 Field Documentation

3.33.2.1 newlogonly

```
WORD HANDLERS::newlogonly
```

Definition at line 916 of file structs.h.

3.33.2.2 newhandle

```
WORD HANDLERS::newhandle
```

Definition at line 917 of file structs.h.

3.33.2.3 oldhandle

```
WORD HANDLERS::oldhandle
```

Definition at line 918 of file structs.h.

3.33.2.4 oldlogonly

```
WORD HANDLERS::oldlogonly
```

Definition at line 919 of file structs.h.

3.33.2.5 oldprinttype

```
WORD HANDLERS::oldprinttype
```

Definition at line 920 of file structs.h.

3.33.2.6 oldsilent

```
WORD HANDLERS::oldsilent
```

Definition at line 921 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.34 InDeX Struct Reference

Data Fields

- LONG name
- WORD type
- WORD dimension
- WORD number
- WORD flags
- WORD nmin4
- WORD node
- WORD namesize

3.34.1 Detailed Description

Definition at line 443 of file structs.h.

3.34.2 Field Documentation

3.34.2.1 name

```
LONG InDeX::name
```

Definition at line 444 of file structs.h.

3.34.2.2 type

```
WORD InDeX::type
```

Definition at line 445 of file structs.h.

3.34.2.3 dimension

```
WORD InDeX::dimension
```

Definition at line 446 of file structs.h.

3.34.2.4 number

```
WORD InDeX::number
```

Definition at line 447 of file structs.h.

3.34.2.5 flags

```
WORD InDeX::flags
```

Definition at line 448 of file structs.h.

3.34.2.6 nmin4

```
WORD InDeX::nmin4
```

Definition at line 449 of file structs.h.

3.34.2.7 node

```
WORD InDeX::node
```

Definition at line 450 of file structs.h.

3.34.2.8 namesize

```
WORD InDeX::namesize
```

Definition at line 451 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.35 indexblock Struct Reference

Collaboration diagram for indexblock:

Data Fields

- MLONG flags
- MLONG previousblock
- MLONG position
- OBJECTS objects [NUMOBJECTS]

3.35.1 Detailed Description

Definition at line 107 of file minos.h.

3.35.2 Field Documentation

3.35.2.1 flags

```
MLONG indexblock::flags
```

Definition at line 108 of file minos.h.

3.35.2.2 previousblock

```
MLONG indexblock::previousblock
```

Definition at line 109 of file minos.h.

3.35.2.3 position

```
MLONG indexblock::position
```

Definition at line 110 of file minos.h.

3.35.2.4 objects

```
OBJECTS indexblock::objects[NUMOBJECTS]
```

Definition at line 111 of file minos.h.

The documentation for this struct was generated from the following file:

- minos.h

3.36 InDeXeNtRy Struct Reference

```
#include <structs.h>
```

Collaboration diagram for InDeXeNtRy:

Public Member Functions

- **PADPOSITION** (0, 1, 0, 5, MAXENAME+1)

Data Fields

- POSITION position
- POSITION length
- POSITION variables
- LONG CompressSize
- WORD nsymbols
- WORD nindices
- WORD nvectors
- WORD nfunctions
- WORD size
- SBYTE name [MAXENAME+1]

3.36.1 Detailed Description

Defines the structure of an entry in a file index (see struct FiLeInDeX).

It represents one expression in the file.

Definition at line 99 of file structs.h.

3.36.2 Field Documentation

3.36.2.1 position

```
POSITION InDeXeNtRy::position
```

Position of the expression itself

Definition at line 100 of file structs.h.

3.36.2.2 length

```
POSITION InDeXeNtRy::length
```

Length of the expression itself

Definition at line 101 of file structs.h.

3.36.2.3 variables

```
POSITION InDeXeNtRy::variables
```

Position of the list with variables

Definition at line 102 of file structs.h.

3.36.2.4 CompressSize

```
LONG InDeXeNtRy::CompressSize
```

Size of buffer before compress

Definition at line 103 of file structs.h.

3.36.2.5 nsymbols

```
WORD InDeXeNtRy::nsymbols
```

Number of symbols in the list

Definition at line 104 of file structs.h.

Referenced by ReadSaveVariables().

3.36.2.6 nindices

```
WORD InDeXeNtRy::nindices
```

Number of indices in the list

Definition at line 105 of file structs.h.

Referenced by ReadSaveVariables().

3.36.2.7 nvectors

```
WORD InDeXeNtRy::nvectors
```

Number of vectors in the list

Definition at line 106 of file structs.h.

Referenced by ReadSaveVariables().

3.36.2.8 nfunctions

```
WORD InDeXeNtRy::nfunctions
```

Number of functions in the list

Definition at line 107 of file structs.h.

Referenced by ReadSaveVariables().

3.36.2.9 size

```
WORD InDeXeNtRy::size
```

Size of variables field

Definition at line 108 of file structs.h.

3.36.2.10 name

```
SBYTE InDeXeNtRy::name[MAXENAME+1]
```

Name of expression

Definition at line 109 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.37 iniinfo Struct Reference

Data Fields

- MLONG entriesinindex
- MLONG numberofindexblocks
- MLONG firstindexblock
- MLONG lastindexblock
- MLONG numberoftables
- MLONG numberofnamesblocks
- MLONG firstnameblock
- MLONG lastnameblock

3.37.1 Detailed Description

Definition at line 82 of file minos.h.

3.37.2 Field Documentation

3.37.2.1 entriesinindex

```
MLONG iniinfo::entriesinindex
```

Definition at line 84 of file minos.h.

3.37.2.2 numberofindexblocks

```
MLONG iniinfo::numberofindexblocks
```

Definition at line 85 of file minos.h.

3.37.2.3 firstindexblock

```
MLONG iniinfo::firstindexblock
```

Definition at line 86 of file minos.h.

3.37.2.4 lastindexblock

```
MLONG iniinfo::lastindexblock
```

Definition at line 87 of file minos.h.

3.37.2.5 numberoftables

```
MLONG iniinfo::numberoftables
```

Definition at line 88 of file minos.h.

3.37.2.6 numberofnamesblocks

```
MLONG iniinfo::numberofnamesblocks
```

Definition at line 89 of file minos.h.

3.37.2.7 firstnameblock

```
MLONG iniinfo::firstnameblock
```

Definition at line 90 of file minos.h.

3.37.2.8 lastnameblock

```
MLONG iniinfo::lastnameblock
```

Definition at line 91 of file minos.h.

The documentation for this struct was generated from the following file:

- minos.h

3.38 INSIDEINFO Struct Reference

```
#include <structs.h>
```

Data Fields

- WORD * buffer
- int oldcompiletype
- int oldparallelflag
- int oldnumpotmoddollars
- WORD size
- WORD numdollars
- WORD oldcbuf
- WORD oldrbuf
- WORD inscbuf
- WORD oldcnumlhs

3.38.1 Detailed Description

Used for #inside

Definition at line 805 of file structs.h.

3.38.2 Field Documentation

3.38.2.1 buffer

```
WORD* INSIDEINFO::buffer
```

Definition at line 806 of file structs.h.

3.38.2.2 oldcompiletype

```
int INSIDEINFO::oldcompiletype
```

Definition at line 807 of file structs.h.

3.38.2.3 oldparallelflag

```
int INSIDEINFO::oldparallelflag
```

Definition at line 808 of file structs.h.

3.38.2.4 oldnumpotmoddollars

```
int INSIDEINFO::oldnumpotmoddollars
```

Definition at line 809 of file structs.h.

3.38.2.5 size

```
WORD INSIDEINFO::size
```

Definition at line 810 of file structs.h.

3.38.2.6 numdollars

```
WORD INSIDEINFO::numdollars
```

Definition at line 811 of file structs.h.

3.38.2.7 oldcbuf

```
WORD INSIDEINFO::oldcbuf
```

Definition at line 812 of file structs.h.

3.38.2.8 oldrbuf

```
WORD INSIDEINFO::oldrbuf
```

Definition at line 813 of file structs.h.

3.38.2.9 inscbuf

```
WORD INSIDEINFO::inscbuf
```

Definition at line 814 of file structs.h.

3.38.2.10 oldcnumlhs

```
WORD INSIDEINFO::oldcnumlhs
```

Definition at line 815 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.39 KEYWORD Struct Reference

```
#include <structs.h>
```

Data Fields

- char * name
- TFUN func
- int type
- int flags

3.39.1 Detailed Description

The KEYWORD struct defines names of commands/statements and the routine to be called when they are encountered by the compiler or preprocessor.

Definition at line 221 of file structs.h.

3.39.2 Field Documentation

3.39.2.1 name

```
char* KEYWORD::name
```

Definition at line 222 of file structs.h.

3.39.2.2 func

```
TFUN KEYWORD::func
```

Definition at line 223 of file structs.h.

3.39.2.3 type

```
int KEYWORD::type
```

Definition at line 224 of file structs.h.

3.39.2.4 flags

```
int KEYWORD::flags
```

Definition at line 225 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.40 KEYWORDV Struct Reference

```
#include <structs.h>
```

Data Fields

- char * name
- int * var
- int type
- int flags

3.40.1 Detailed Description

The KEYWORDV struct defines names of commands/statements and the variable to be affected when they are encountered by the compiler or preprocessor.

Definition at line 233 of file structs.h.

3.40.2 Field Documentation

3.40.2.1 name

```
char* KEYWORDV::name
```

Definition at line 234 of file structs.h.

3.40.2.2 var

```
int* KEYWORDV::var
```

Definition at line 235 of file structs.h.

3.40.2.3 type

```
int KEYWORDV::type
```

Definition at line 236 of file structs.h.

3.40.2.4 flags

```
int KEYWORDV::flags
```

Definition at line 237 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.41 LIST Struct Reference

```
#include <structs.h>
```

Data Fields

- void * lijst
- char * message
- int num
- int maxnum
- int size
- int numglobal
- int numtemp
- int numclear

3.41.1 Detailed Description

Much information is stored in arrays of which we can double the size if the array proves to be too small. Such arrays are controled by a variable of type LIST. The routines that expand the lists are in the file tools.c

Definition at line 204 of file structs.h.

3.41.2 Field Documentation

3.41.2.1 lijst

```
void* LIST::lijst
```

[D] Holds space for "maxnum" elements of size "size" each

Definition at line 205 of file structs.h.

3.41.2.2 message

```
char* LIST::message
```

Text for Malloc1 when allocating lijst. Set to constant string.

Definition at line 206 of file structs.h.

3.41.2.3 num

```
int LIST::num
```

Number of elements in lijst.

Definition at line 207 of file structs.h.

3.41.2.4 maxnum

```
int LIST::maxnum
```

Maximum number of elements in lijst.

Definition at line 208 of file structs.h.

3.41.2.5 size

```
int LIST::size
```

Size of one element in lijst.

Definition at line 209 of file structs.h.

3.41.2.6 numglobal

```
int LIST::numglobal
```

Marker for position when .global is executed.

Definition at line 210 of file structs.h.

3.41.2.7 numtemp

```
int LIST::numtemp
```

At the moment only needed for sets and setstore.

Definition at line 211 of file structs.h.

3.41.2.8 numclear

```
int LIST::numclear
```

Only for the clear instruction.

Definition at line 212 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.42 longMultiStruct Struct Reference

Collaboration diagram for longMultiStruct:

Data Fields

- UBYTE * buffer
- int bufpos
- int packpos
- int nPacks
- int lastLen
- struct longMultiStruct * next

3.42.1 Detailed Description

Definition at line 1013 of file mpi.c.

3.42.2 Field Documentation

3.42.2.1 buffer

```
UBYTE* longMultiStruct::buffer
```

Definition at line 1014 of file mpi.c.

3.42.2.2 bufpos

```
int longMultiStruct::bufpos
```

Definition at line 1015 of file mpi.c.

3.42.2.3 packpos

```
int longMultiStruct::packpos
```

Definition at line 1016 of file mpi.c.

3.42.2.4 nPacks

```
int longMultiStruct::nPacks
```

Definition at line 1017 of file mpi.c.

3.42.2.5 lastLen

```
int longMultiStruct::lastLen
```

Definition at line 1018 of file mpi.c.

3.42.2.6 next

```
struct longMultiStruct* longMultiStruct::next
```

Definition at line 1021 of file mpi.c.

The documentation for this struct was generated from the following file:

3.43.1 Detailed Description

The M_const struct is part of the global data and resides in the ALLGLOBALS struct A under the name #M. We see it used with the macro AM as in AM.S0. It contains global settings at startup or .clear.

Definition at line 1360 of file structs.h.

3.43.2 Field Documentation

3.43.2.1 zeropos

```
POSITION M_const::zeropos
```

Definition at line 1361 of file structs.h.

3.43.2.2 S0

```
SORTING* M_const::S0
```

[D] The main sort buffer

Definition at line 1362 of file structs.h.

3.43.2.3 gcmod

```
UWORD* M_const::gcmod
```

Global setting of modulus. Uses AC.cmod's memory

Definition at line 1363 of file structs.h.

3.43.2.4 gpowmod

```
UWORD* M_const::gpowmod
```

Global setting printing as powers. Uses AC.cmod's memory

Definition at line 1364 of file structs.h.

3.43.2.5 TempDir

```
UBYTE* M_const::TempDir
```

Definition at line 1365 of file structs.h.

3.43.2.6 TempSortDir

```
UBYTE* M_const::TempSortDir
```

Definition at line 1366 of file structs.h.

3.43.2.7 IncDir

```
UBYTE* M_const::IncDir
```

Definition at line 1367 of file structs.h.

3.43.2.8 InputFileName

```
UBYTE* M_const::InputFileName
```

3.45 MiNmAx Struct Reference

Data Fields

- WORD mini
- WORD maxi
- WORD size

3.45.1 Detailed Description

Definition at line 306 of file structs.h.

3.45.2 Field Documentation

3.45.2.1 mini

```
WORD MiNmAx::mini
```

Minimum value

Definition at line 307 of file structs.h.

Referenced by TestSub().

3.45.2.2 maxi

```
WORD MiNmAx::maxi
```

Maximum value

Definition at line 308 of file structs.h.

Referenced by TestSub().

3.45.2.3 size

```
WORD MiNmAx::size
```

Value of one unit in this position.

Definition at line 309 of file structs.h.

Referenced by TestSub().

The documentation for this struct was generated from the following file:

3.50.1 Detailed Description

The N_const struct is part of the global data and resides either in the ALLGLOBALS struct A, or the ALLPRIVATES struct B (TFORM) under the name N We see it used with the macro AN as in AN.RepFunNum It has variables that are private to each thread and are used as temporary storage during the expansion of the terms tree.

char nameblock::names[NAMETABLESIZE]
```

Definition at line 117 of file minos.h.

The documentation for this struct was generated from the following file:

- minos.h

3.52 NaMeNode Struct Reference

```
#include <structs.h>
```

Data Fields

- LONG name
- WORD parent
- WORD left
- WORD right
- WORD balance
- WORD type
- WORD number

3.52.1 Detailed Description

The names of variables are kept in an array. Elements of type NAMENODE define a tree (that is kept balanced) that make it easy and fast to look for variables. See also NAMETREE.

Definition at line 246 of file structs.h.

3.52.2 Field Documentation

3.52.2.1 name

```
LONG NaMeNode::name
```

Offset into NAMETREE::namebuffer.

Definition at line 247 of file structs.h.

3.52.2.2 parent

```
WORD NaMeNode::parent
```

=-1 if no parent.

Definition at line 248 of file structs.h.

3.52.2.3 left

```
WORD NaMeNode::left
```

=-1 if no child.

Definition at line 249 of file structs.h.

3.52.2.4 right

```
WORD NaMeNode::right
```

=-1 if no child.

Definition at line 250 of file structs.h.

3.52.2.5 balance

```
WORD NaMeNode::balance
```

Used for the balancing of the tree.

Definition at line 251 of file structs.h.

3.52.2.6 type

```
WORD NaMeNode::type
```

Type associated with the name. See compiler types.

Definition at line 252 of file structs.h.

3.52.2.7 number

```
WORD NaMeNode::number
```

Number of variable in LIST's like for example C_const::SymbolList.

Definition at line 253 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.53 NaMeTree Struct Reference

```
#include <structs.h>
```

Collaboration diagram for NaMeTree:

Data Fields

- NAMENODE * namenode
- UBYTE * namebuffer
- LONG nodesize
- LONG nodefill
- LONG namesize
- LONG namefill
- LONG oldnamefill
- LONG oldnodefill
- LONG globalnamefill
- LONG globalnodefill
- LONG clearnamefill
- LONG clearnodefill
- WORD headnode

3.53.1 Detailed Description

A struct of type NAMETREE controls a complete (balanced) tree of names for the compiler. The compiler maintains several of such trees and the system has been set up in such a way that one could define more of them if we ever want to work with local name spaces.

Definition at line 264 of file structs.h.

3.53.2 Field Documentation

3.53.2.1 namenode

```
NAMENODE* NaMeTree::namenode
```

[D] Vector of NAMENODE's. Number of elements is nodesize. =0 if no memory has been allocated.

Definition at line 265 of file structs.h.

3.53.2.2 namebuffer

```
UBYTE* NaMeTree::namebuffer
```

[D] Buffer that holds all the name strings refered to by the NAMENODE's. Allocation size is namesize. =0 if no memory has been allocated.

Definition at line 267 of file structs.h.

3.53.2.3 nodesize

```
LONG NaMeTree::nodesize
```

Maximum number of elements in namenode.

Definition at line 270 of file structs.h.

3.53.2.4 nodefill

```
LONG NaMeTree::nodefill
```

Number of currently used nodes in namenode.

Definition at line 271 of file structs.h.

3.53.2.5 namesize

```
LONG NaMeTree::namesize
```

Allocation size of namebuffer in bytes.

Definition at line 272 of file structs.h.

3.53.2.6 namefill

```
LONG NaMeTree::namefill
```

Number of bytes occupied.

Definition at line 273 of file structs.h.

3.53.2.7 oldnamefill

```
LONG NaMeTree::oldnamefill
```

UNUSED

Definition at line 274 of file structs.h.

3.53.2.8 oldnodefill

```
LONG NaMeTree::oldnodefill
```

UNUSED

Definition at line 275 of file structs.h.

3.53.2.9 globalnamefill

```
LONG NaMeTree::globalnamefill
```

Set by .global statement to the value of namefill. When a .store command is processed, this value will be used to reset namefill.

Definition at line 276 of file structs.h.

3.53.2.10 globalnodefill

```
LONG NaMeTree::globalnodefill
```

Same usage as globalnamefill, but for nodefill.

Definition at line 278 of file structs.h.

3.53.2.11 clearnamefill

```
LONG NaMeTree::clearnamefill
```

Marks the reset point used by the .clear statement.

Definition at line 279 of file structs.h.

3.53.2.12 clearnodefill

```
LONG NaMeTree::clearnodefill
```

Marks the reset point used by the .clear statement.

Definition at line 280 of file structs.h.

3.53.2.13 headnode

```
WORD NaMeTree::headnode
```

Offset in namenode of head node. =-1 if tree is empty.

Definition at line 281 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.54 NeStInG Struct Reference

```
#include <structs.h>
```

Data Fields

- WORD * termsize
- WORD * funsize
- WORD * argsize

3.54.1 Detailed Description

The NESTING struct is used when we enter the argument of functions and there is the possibility that we have to change something there. Because functions can be nested we have to keep track of all levels of functions in case we have to move the outer layers to make room for a larger function argument.

Definition at line 999 of file structs.h.

3.54.2 Field Documentation

3.54.2.1 termsize

```
WORD* NeStInG::termsize
```

Definition at line 1000 of file structs.h.

3.54.2.2 funsize

```
WORD* NeStInG::funsize
```

Definition at line 1001 of file structs.h.

3.54.2.3 argsize

```
WORD* NeStInG::argsize
```

Definition at line 1002 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.60.1 Detailed Description

The P_const struct is part of the global data and resides in the ALLGLOBALS struct A under the name P We see it used with the macro AP as in AP.InOutBuf It contains objects that have dealings with the preprocessor.

Definition at line 1548 of file structs.h.

3.67 POLYMOD Struct Reference

```
#include <structs.h>
```

Data Fields

- WORD * coefs
- WORD numsym
- WORD arraysize
- WORD polysize
- WORD modnum

3.67.1 Detailed Description

The POLYMOD struct controls one univariate polynomial of which the coefficients have been taken modulus a (prime) number that fits inside a variable of type WORD. The polynomial is stored as an array of coefficients of size WORD.

Definition at line 1215 of file structs.h.

3.67.2 Field Documentation

3.67.2.1 coefs

```
WORD* POLYMOD::coefs
```

Definition at line 1216 of file structs.h.

3.67.2.2 numsym

```
WORD POLYMOD::numsym
```

Definition at line 1217 of file structs.h.

3.67.2.3 arraysize

```
WORD POLYMOD::arraysize
```

Definition at line 1218 of file structs.h.

3.67.2.4 polysize

```
WORD POLYMOD::polysize
```

Definition at line 1219 of file structs.h.

3.67.2.5 modnum

```
WORD POLYMOD::modnum
```

Definition at line 1220 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.68 PoSiTiOn Struct Reference

Data Fields

- off_t p1

3.68.1 Detailed Description

Definition at line 58 of file structs.h.

3.68.2 Field Documentation

3.68.2.1 p1

```
off_t PoSiTiOn::p1
```

Definition at line 59 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.69 PRELOAD Struct Reference

```
#include <structs.h>
```

Data Fields

- UBYTE * buffer
- LONG size

3.69.1 Detailed Description

Used by the preprocessor to load the contents of a doloop or a procedure. The struct PRELOAD is used both in the DOLOOP and PROCEDURE structs.

Definition at line 824 of file structs.h.

3.69.2 Field Documentation

3.69.2.1 buffer

```
UBYTE* PRELOAD::buffer
```

Definition at line 825 of file structs.h.

3.69.2.2 size

```
LONG PRELOAD::size
```

Definition at line 826 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.70 pReVaR Struct Reference

```
#include <structs.h>
```

Data Fields

- UBYTE * name
- UBYTE * value
- UBYTE * argnames
- int nargs
- int wildarg

3.70.1 Detailed Description

An element of the type PREVAR is needed for each preprocessor variable.

Definition at line 792 of file structs.h.

3.70.2 Field Documentation

3.70.2.1 name

```
UBYTE* pReVaR::name
```

allocated

Definition at line 793 of file structs.h.

Referenced by PutPreVar().

3.70.2.2 value

```
UBYTE* pReVaR::value
```

points into memory of name

Definition at line 794 of file structs.h.

Referenced by PutPreVar().

3.70.2.3 argnames

```
UBYTE* pReVaR::argnames
```

names of arguments, zero separated. points into memory of name

Definition at line 795 of file structs.h.

Referenced by PutPreVar().

3.70.2.4 nargs

```
int pReVaR::nargs
```

0 = regular, >= 1: number of macro arguments. total number

Definition at line 796 of file structs.h.

Referenced by PutPreVar().

3.70.2.5 wildarg

```
int pReVaR::wildarg
```

The number of a potential ?var. If none: 0. wildarg<nargs

Definition at line 797 of file structs.h.

Referenced by PutPreVar().

The documentation for this struct was generated from the following file:

- structs.h

3.71 PROCEDURE Struct Reference

```
#include <structs.h>
```

Collaboration diagram for PROCEDURE:

Data Fields

- PRELOAD p
- UBYTE * name
- int loadmode

3.71.1 Detailed Description

An element of the type PROCEDURE is needed for each procedure in the system.

3.72.1 Detailed Description

The R_const struct is part of the global data and resides either in the ALLGLOBALS struct A, or the ALLPRIVATES struct B (TFORM) under the name R We see it used with the macro AR as in AR.infile It has the variables that define the running environment and that should be transferred with a term in a multithreaded run.

3.76 SETUPPARAMETERS Struct Reference

```
#include <structs.h>
```

Data Fields

- UBYTE * parameter
- int type
- int flags
- LONG value

3.76.1 Detailed Description

Each setup parameter has one element of the struct SETUPPARAMETERS assigned to it. By binary search in the array of them we can then locate the proper element by name. We have to assume that two ints make a long and either one or two longs make a pointer. The long before the ints and padding gives a problem in the initialization.

3.78.1 Detailed Description

The struct SORTING is used to control a sort operation. It includes a small and a large buffer and arrays for keeping track of various stages of the (merge) sorts. Each sort level has its own struct and different levels can have different sizes for its arrays. Also different threads have their own set of SORTING structs.

#include <structs.h>
```

Data Fields

- UBYTE headermark [8]
- UBYTE lenWORD
- UBYTE lenLONG
- UBYTE lenPOS
- UBYTE lenPOINTER
- UBYTE endianness [16]
- UBYTE sSym
- UBYTE sInd
- UBYTE sVec
- UBYTE sFun
- UBYTE maxpower [16]
- UBYTE wildoffset [16]
- UBYTE revision
- UBYTE reserved [512-8-4-16-4-16-16-1]

3.81.1 Detailed Description

Defines the structure of the file header for store-files and save-files.

The first 8 bytes serve as a unique mark to identity save-files that contain such a header. Older versions of FORM don't have this header and will write the POSITION of the next file index (struct FiLeInDeX) here, which is always different from this pattern.

It is always 512 bytes long.

Definition at line 74 of file structs.h.

3.81.2 Field Documentation

3.81.2.1 headermark

```
UBYTE STOREHEADER::headermark[8]
```

Pattern for header identification. Old versions of FORM have a maximum sizeof(POSITION) of 8

Definition at line 75 of file structs.h.

3.81.2.2 lenWORD

```
UBYTE STOREHEADER::lenWORD
```

Number of bytes for WORD

Definition at line 77 of file structs.h.

Referenced by WriteStoreHeader().

3.81.2.3 lenLONG

```
UBYTE STOREHEADER::lenLONG
```

Number of bytes for LONG

Definition at line 78 of file structs.h.

Referenced by WriteStoreHeader().

3.81.2.4 lenPOS

```
UBYTE STOREHEADER::lenPOS
```

Number of bytes for POSITION

Definition at line 79 of file structs.h.

Referenced by WriteStoreHeader().

3.81.2.5 lenPOINTER

```
UBYTE STOREHEADER::lenPOINTER
```

Number of bytes for void *

Definition at line 80 of file structs.h.

Referenced by WriteStoreHeader().

3.81.2.6 endianness

```
UBYTE STOREHEADER::endianness[16]
```

Used to determine endianness, sizeof(int) should be <= 16

Definition at line 81 of file structs.h.

Referenced by WriteStoreHeader().

3.81.2.7 sSym

```
UBYTE STOREHEADER::sSym
```

sizeof(struct SyMbOl)

Definition at line 82 of file structs.h.

Referenced by WriteStoreHeader().

3.81.2.8 sInd

```
UBYTE STOREHEADER::sInd
```

sizeof(struct InDeX)

Definition at line 83 of file structs.h.

Referenced by WriteStoreHeader().

3.82.1 Detailed Description

Input is read from 'streams' which are represented by objects of type STREAM. A stream can be a file, a do-loop, a procedure, the string value of a preprocessor variable ..... When a new stream is opened we have to keep information about where to fall back in the parent stream to allow this to happen even in the middle of reading names etc as would be the case with a`i'b

3.90.1 Detailed Description

buffers, mm, flags, and prototype are always dynamically allocated, tablepointers only if needed (=0 if unallocated), boomlijst and argtail only for sparse tables.

Allocation is done for both the normal and the stub instance (spare), except for prototype and argtail which share memory.

Definition at line 349 of file structs.h.

3.90.2 Field Documentation

3.90.2.1 tablepointers

```
WORD* TaBlEs::tablepointers
```

[D] Start in tablepointers table.

3.90.2.2 prototype

```
WORD* TaBlEs::prototype
```

[D] The wildcard prototyping for arguments

Definition at line 355 of file structs.h.

Referenced by DoRecovery(), and TestSub().

3.90.2.3 pattern

```
WORD* TaBlEs::pattern
```

The pattern with which to match the arguments

Definition at line 356 of file structs.h.

Referenced by DoRecovery(), and TestSub().

3.90.2.4 mm

```
MINMAX* TaBlEs::mm
```

[D] Array bounds, dimension by dimension. # elements = numind.

Definition at line 358 of file structs.h.

Referenced by DoRecovery(), and TestSub().

3.90.2.5 flags

```
WORD* TaBlEs::flags
```

[D] Is element in use ? etc. # elements = numind.

Definition at line 359 of file structs.h.

Referenced by DoRecovery().

3.90.2.6 boomlijst

```
COMPTREE* TaBlEs::boomlijst
```

[D] Tree for searching in sparse tables

Definition at line 360 of file structs.h.

Referenced by DoRecovery().

3.90.2.7 argtail

```
UBYTE* TaBlEs::argtail
```

[D] The arguments in characters. Starts for tablebase with parenthesis to indicate tail

Definition at line 361 of file structs.h.

Referenced by DoRecovery().

3.90.2.8 spare

```
struct TaBlEs* TaBlEs::spare
```

[D] For tablebase. Alternatingly stubs and real

Definition at line 363 of file structs.h.

Referenced by DoRecovery().

3.90.2.9 buffers

```
WORD* TaBlEs::buffers
```

[D] When we use more than one compiler buffer.

Definition at line 364 of file structs.h.

Referenced by AddRHS(), and DoRecovery().

3.90.2.10 totind

```
LONG TaBlEs::totind
```

Total number requested

Definition at line 365 of file structs.h.

Referenced by DoRecovery().

3.90.2.11 reserved

```
LONG TaBlEs::reserved
```

Total reservation in tablepointers for sparse

Definition at line 366 of file structs.h.

Referenced by DoRecovery().

3.90.2.12 defined

```
LONG TaBlEs::defined
```

Number of table elements that are defined

Definition at line 367 of file structs.h.

3.90.2.13 mdefined

```
LONG TaBlEs::mdefined
```

Same as defined but after .global

Definition at line 368 of file structs.h.

3.90.2.14 prototypeSize

```
int TaBlEs::prototypeSize
```

Size of allocated memory for prototype in bytes.

Definition at line 369 of file structs.h.

Referenced by DoRecovery().

3.90.2.15 numind

```
int TaBlEs::numind
```

Number of array indices

Definition at line 370 of file structs.h.

Referenced by DoRecovery(), and TestSub().

3.90.2.16 bounds

```
int TaBlEs::bounds
```

Array bounds check on/off.

Definition at line 371 of file structs.h.

Referenced by TestSub().

3.90.2.17 strict

```
int TaBlEs::strict
```

>0: all must be defined. <0: undefined not substitute

Definition at line 372 of file structs.h.

3.92.1 Detailed Description

The struct TRACES keeps track of the progress during the expansion of a 4-dimensional trace. Each time a term gets generated the expansion tree continues in the next statement. When it returns it has to know where to continue. The 4-dimensional traces are more complicated than the n-dimensional traces (see TRACEN) because of the extra tricks that can be used. They are responsible for the shorter final expressions.

Definition at line 740 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.93 tree Struct Reference

```
#include <structs.h>
```

Data Fields

- int parent
- int left
- int right
- int value
- int blnce
- int usage

3.93.1 Detailed Description

The subexpressions in the compiler are kept track of in a (balanced) tree to reduce the need for subexpressions and hence save much space in large rhs expressions (like when we have xxxxxxx occurrences of objects like f(x+1,x+1) in which each x+1 becomes a subexpression. The struct that controls this tree is COMPTREE.

Definition at line 293 of file structs.h.

3.93.2 Field Documentation

3.93.2.1 parent

```
int tree::parent
```

Index of parent

Definition at line 294 of file structs.h.

Referenced by IniFbuffer().

3.93.2.2 left

```
int tree::left
```

Left child (if not -1)

Definition at line 295 of file structs.h.

Referenced by IniFbuffer().

3.93.2.3 right

```
int tree::right
```

Right child (if not -1)

Definition at line 296 of file structs.h.

Referenced by IniFbuffer().

3.93.2.4 value

```
int tree::value
```

The object to be sorted and searched

Definition at line 297 of file structs.h.

Referenced by IniFbuffer().

3.93.2.5 blnce

```
int tree::blnce
```

Balance factor

Definition at line 298 of file structs.h.

Referenced by IniFbuffer().

3.93.2.6 usage

```
int tree::usage
```

Number of uses in some types of trees

Definition at line 299 of file structs.h.

Referenced by CleanupArgCache(), and IniFbuffer().

The documentation for this struct was generated from the following file:

- structs.h

3.94 VaRrEnUm Struct Reference

```
#include <structs.h>
```

Data Fields

- WORD * start
- WORD * lo
- WORD * hi

3.94.1 Detailed Description

Contains the pointers to an array in which a binary search will be performed.

Definition at line 165 of file structs.h.

3.94.2 Field Documentation

3.94.2.1 start

```
WORD* VaRrEnUm::start
```

Start point for search. Points inbetween lo and hi

Definition at line 166 of file structs.h.

Referenced by DoRecovery().

3.94.2.2 lo

```
WORD* VaRrEnUm::lo
```

Start of memory area

Definition at line 167 of file structs.h.

Referenced by DoRecovery(), and Generator().

3.94.2.3 hi

```
WORD* VaRrEnUm::hi
```

End of memory area

Definition at line 168 of file structs.h.

Referenced by DoRecovery().

The documentation for this struct was generated from the following file:

- structs.h

3.95 VeCtOr Struct Reference

Data Fields

4.1.1 Detailed Description

Contains the routines that deal with the execution phase of the argument and related statements (like term)

Definition in file argument.c.

4.1.2 Macro Definition Documentation

4.1.2.1 NEWORDER

```
#define NEWORDER
```

Factorizes an argument in general notation (meaning that the first word of the argument is a positive size indicator) Input (argin): pointer to the complete argument Output (argout): Pointer to where the output should be written. This is in the WorkSpace Return value should be negative if anything goes wrong.

The notation of the output should be a string of arguments terminated by the number zero.

Originally we sorted in a way that the constants came last. This gave conflicts with the dollar and expression factorizations (in the expressions we wanted the zero first and then followed by the constants).

Definition at line 2013 of file argument.c.

4.1.3 Function Documentation

4.1.3.1 execarg()

```
WORD execarg (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 56 of file argument.c.

4.1.3.2 execterm()

```
WORD execterm (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 1724 of file argument.c.

4.1.3.3 ArgumentImplode()

```
int ArgumentImplode (
            PHEAD WORD * term,
            WORD * thelist )
```

Definition at line 1800 of file argument.c.

4.1.3.4 ArgumentExplode()

```
int ArgumentExplode (
            PHEAD WORD * term,
            WORD * thelist )
```

Definition at line 1904 of file argument.c.

4.1.3.5 ArgFactorize()

```
int ArgFactorize (
            PHEAD WORD * argin,
            WORD * argout )
```

Definition at line 2015 of file argument.c.

4.1.3.6 FindArg()

```
WORD FindArg (
            PHEAD WORD * a )
```

Looks the argument up in the (workers) table. If it is found the number in the table is returned (plus one to make it positive). If it is not found we look in the compiler provided table. If it is found - the number in the table is returned (minus one to make it negative). If in neither table we return zero.

Definition at line 2463 of file argument.c.

4.1.3.7 InsertArg()

```
WORD InsertArg (
            PHEAD WORD * argin,
            WORD * argout,
            int par )
```

Inserts the argument into the (workers) table. If the table is too full we eliminate half of it. The eliminated elements are the ones that have not been used most recently, weighted by their total use and age(?). If par == 0 it inserts in the regular factorization cache If par == 1 it inserts in the cache defined with the FactorCache statement

Definition at line 2487 of file argument.c.

References AddNtoC(), AddRHS(), and CleanupArgCache().

Here is the call graph for this function:

4.1.3.8 CleanupArgCache()

```
int CleanupArgCache (
            PHEAD WORD bufnum )
```

Cleans up the argument factorization cache. We throw half the elements. For a weight of what we want to keep we use the product of usage and the number in the buffer.

Definition at line 2522 of file argument.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::Pointer, CbUf::rhs, SortWeights(), and tree::usage.

Referenced by InsertArg().

Here is the call graph for this function:

4.1.3.9 ArgSymbolMerge()

```
int ArgSymbolMerge (
            WORD * t1,
            WORD * t2 )
```

Definition at line 2593 of file argument.c.

4.1.3.10 ArgDotproductMerge()

```
int ArgDotproductMerge (
            WORD * t1,
            WORD * t2 )
```

Definition at line 2648 of file argument.c.

4.1.3.11 TakeArgContent()

```
WORD * TakeArgContent (
            PHEAD WORD * argin,
            WORD * argout )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. The common pieces are put in argout as a sequence of arguments. The part with the multiple terms that are now relative prime is put in argfree which is allocated via TermMalloc and is given as the return value. The difference with the old code is that negative powers are always removed. Hence it is as in MakeInteger in which only numerators will be left: now only zero or positive powers will be remaining.

Definition at line 2716 of file argument.c.

References EndSort(), MakeInteger(), MakeMod(), NewSort(), and StoreTerm().

Here is the call graph for this function:

4.1.3.12 MakeInteger()

```
WORD * MakeInteger (
            PHEAD WORD * argin,
            WORD * argout,
            WORD * argfree )
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in argin. The number that comes out should go to argout. The new pointer in the argout buffer is the return value. The normalized argument is in argfree.

Definition at line 3262 of file argument.c.

Referenced by TakeArgContent().

4.1.3.13 MakeMod()

```
WORD * MakeMod (
            PHEAD WORD * argin,
            WORD * argout,
            WORD * argfree )
```

Similar to MakeInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3433 of file argument.c.

References GetModInverses().

Referenced by TakeArgContent().

Here is the call graph for this function:

4.1.3.14 SortWeights()

```
void SortWeights (
            LONG * weights,
            LONG * extraspace,
            WORD number )
```

Sorts an array of LONGS in the same way SplitMerge (in sort.c) works We use gradual division in two.

Definition at line 3478 of file argument.c.

References SortWeights().

Referenced by CleanupArgCache(), and SortWeights().

Here is the call graph for this function:

- void DoCheckpoint (int moduletype)

Variables

- unsigned char cache_buffer [CACHE_SIZE]
- size_t cache_fill = 0

4.5.1 Detailed Description

Contains all functions that deal with the recovery mechanism controlled and activated by the On Checkpoint switch.

The main function are DoCheckpoint, DoRecovery, and DoSnapshot. If the checkpoints are activated DoCheckpoint is called every time a module is finished executing. If the conditions for the creation of a recovery snapshot are met DoCheckpoint calls DoSnapshot. DoRecovery is called once when FORM starts up with the command line argument -R. Most of the other code contains debugging facilities that are only compiled if the macro PRINTDEBUG is defined.

The recovery mechanism is atomic, i.e. only if everything went well, the final recovery file is created (and the older one overwritten) in a single step (copying). If some errors occur, a warning is issued and the program continues without having created a new recovery file. The only situation in which the creation of the recovery data leads to a termination of the running program is if not enough disk or memory space is left.

For ParFORM each slave creates its own recovery file, sends it to the master and then it deletes the recovery file. The master stores all the recovery files and on recovery it feeds these files to the slaves. It is nearly impossible to recover after some MPI fault so ParFORM terminates on any recovery failure.

DoRecovery and DoSnapshot do the loading and saving of the recovery data, respectively. Every change in one functions needs to be accompanied by the appropriate change in the other function. The structure of both functions is quite similar. They handle the relevant global structs one after the other and then care about the copying of the hide and scratch files.

The names of the recovery, scratch and hide files are hard-coded in the variables in fold "filenames and system commands".

If the global structs AM,AP,AC,AR are changed, DoRecovery and DoSnapshot usually also have to be changed. Some structs are read/written as a whole (AP,AC), some are read/written only partly as a selection of their individual elements (AM,AR). If AM or AR have been changed by adding or removing an element that is important for the runtime status, then the reading/writing statements have to be added to or removed from DoRecovery and Do↩Snapshot. If AP or AC are changed, then for non-pointer variables (in the case of a struct it also means that none of its elements is a pointer) nothing has to be changed in the functions here. If pointers are involved, extra code has to be added (or removed). See the comments of DoRecovery and DoSnapshot.

4.5.2 Macro Definition Documentation

4.5.2.1 CACHED_SNAPSHOT

```
#define CACHED_SNAPSHOT
```

Definition at line 1211 of file checkpoint.c.

4.5.2.2 CACHE_SIZE

```
#define CACHE_SIZE 4096
```

Definition at line 1213 of file checkpoint.c.

4.5.2.3 R_FREE

```
#define R_FREE(
            ARG )  if ( ARG ) M_free(ARG, #ARG);
```

Definition at line 1278 of file checkpoint.c.

4.5.2.4 R_FREE_NAMETREE

```
#define R_FREE_NAMETREE(
            ARG )
```

Value:

```
R_FREE(ARG->namenode); \
R_FREE(ARG->namebuffer); \
R_FREE(ARG);
```

Definition at line 1281 of file checkpoint.c.

4.5.2.5 R_FREE_STREAM

```
#define R_FREE_STREAM(
              ARG )
```

Value:

```
R_FREE(ARG.buffer); \
R_FREE(ARG.FoldName); \
R_FREE(ARG.name);
```

Definition at line 1286 of file checkpoint.c.

4.5.2.6 R_SET

```
#define R_SET(
              VAR,
              TYPE )  VAR = *((TYPE*)p); p = (unsigned char*)p + sizeof(TYPE);
```

Definition at line 1293 of file checkpoint.c.

4.5.2.7 R_COPY_B

```
#define R_COPY_B(
              VAR,
              SIZE,
              CAST )
```

Value:

```
VAR = (CAST)Malloc1(SIZE,#VAR); \
memcpy(VAR, p, SIZE); p = (unsigned char*)p + SIZE;
```

Definition at line 1298 of file checkpoint.c.

4.5.2.8 S_WRITE_B

```
#define S_WRITE_B(
              BUF,
              LEN )  if ( fwrite_cached(BUF, 1, LEN, fd) != (size_t)(LEN) ) return(__LINE__);
```

Definition at line 1302 of file checkpoint.c.

4.5.2.9 S_FLUSH_B

```
#define S_FLUSH_B  if ( flush_cache(fd) != 1 ) return(__LINE__);
```

Definition at line 1305 of file checkpoint.c.

4.5.2.10 R_COPY_S

```
#define R_COPY_S(
                VAR,
                CAST )
```

Value:

```
    if ( VAR ) { \
        VAR = (CAST)Malloc1(strlen(p)+1,"R_COPY_S"); \
        strcpy((char*)VAR, p); p = (unsigned char*)p + strlen(p) + 1; \
    }
```

Definition at line 1310 of file checkpoint.c.

4.5.2.11 S_WRITE_S

```
#define S_WRITE_S(
                STR )
```

Value:

```
    if ( STR ) { \
        l = strlen((char*)STR) + 1; \
        if ( fwrite_cached(STR, 1, l, fd) != (size_t)l ) return(__LINE__); \
    }
```

Definition at line 1316 of file checkpoint.c.

4.5.2.12 R_COPY_LIST

```
#define R_COPY_LIST(
                ARG )
```

Value:

```
    if ( ARG.maxnum ) { \
        R_COPY_B(ARG.lijst, ARG.size*ARG.maxnum, void*) \
    }
```

Definition at line 1324 of file checkpoint.c.

4.5.2.13 S_WRITE_LIST

```
#define S_WRITE_LIST(
                LST )
```

Value:

```
    if ( LST.maxnum ) { \
        S_WRITE_B((char*)LST.lijst, LST.maxnum*LST.size) \
    }
```

Definition at line 1329 of file checkpoint.c.

4.5.2.14 R_COPY_NAMETREE

```
#define R_COPY_NAMETREE(
            ARG )
```

Value:

```
R_COPY_B(ARG, sizeof(NAMETREE), NAMETREE*); \
if ( ARG->namenode ) { \
    R_COPY_B(ARG->namenode, ARG->nodesize*sizeof(NAMENODE), NAMENODE*); \
} \
if ( ARG->namebuffer ) { \
    R_COPY_B(ARG->namebuffer, ARG->namesize, UBYTE*); \
}
```

Definition at line 1336 of file checkpoint.c.

4.5.2.15 S_WRITE_NAMETREE

```
#define S_WRITE_NAMETREE(
            ARG )
```

Value:

```
S_WRITE_B(ARG, sizeof(NAMETREE)); \
if ( ARG->namenode ) { \
    S_WRITE_B(ARG->namenode, ARG->nodesize*sizeof(struct NaMeNode)); \
} \
if ( ARG->namebuffer ) { \
    S_WRITE_B(ARG->namebuffer, ARG->namesize); \
}
```

Definition at line 1345 of file checkpoint.c.

4.5.2.16 S_WRITE_DOLLAR

```
#define S_WRITE_DOLLAR(
            ARG )
```

Value:

```
if ( ARG.size && ARG.where && ARG.where != &(AM.dollarzero) ) { \
    S_WRITE_B(ARG.where, ARG.size*sizeof(WORD)) \
}
```

Definition at line 1356 of file checkpoint.c.

4.5.2.17 ANNOUNCE

```
#define ANNOUNCE(
            str )
```

Definition at line 1367 of file checkpoint.c.

4.5.3 Function Documentation

4.5.3.1 CheckRecoveryFile()

```
int CheckRecoveryFile ( )
```

Checks whether a snapshot/recovery file exists. Returns 1 if it exists, 0 otherwise.

Definition at line 278 of file checkpoint.c.

References RecoveryFilename().

Here is the call graph for this function:

4.5.3.2 DeleteRecoveryFile()

```
void DeleteRecoveryFile ( )
```

Deletes the recovery files. It is called by CleanUp() in the case of a successful completion.

Definition at line 333 of file checkpoint.c.

4.5.3.3 RecoveryFilename()

```
char * RecoveryFilename ( )
```

Returns pointer to recovery filename.

Definition at line 364 of file checkpoint.c.

Referenced by CheckRecoveryFile(), and DoRecovery().

4.5.3.4 InitRecovery()

```
void InitRecovery ( )
```

Sets up the strings for the filenames of the recovery files. This functions should only be called once to avoid memory leaks and after AM.TempDir has been initialized.

Definition at line 399 of file checkpoint.c.

4.5.3.5 fwrite_cached()

```
size_t fwrite_cached (
            const void * ptr,
            size_t size,
            size_t nmemb,
            FILE * fd )
```

Definition at line 1219 of file checkpoint.c.

4.5.3.6 flush_cache()

```
size_t flush_cache (
            FILE * fd )
```

Definition at line 1244 of file checkpoint.c.

4.5.3.7 DoRecovery()

```
int DoRecovery (
            int * moduletype )
```

Reads from the recovery file and restores all necessary variables and states in FORM, so that the execution can recommence in preprocessor() as if no restart of FORM had occurred.

The recovery file is read into memory as a whole. The pointer p then points into this memory at the next non-processed data. The macros by which variables are restored, like R_SET, automatically increase p appropriately.

If something goes wrong, the function returns with a non-zero value.

Allocated memory that would be lost when overwriting the global structs with data from the file is freed first. A major part of the code deals with the restoration of pointers. The idiom we use is to memorize the original pointer value (org), allocate new memory and copy the data from the file into this memory, calculate the offset between the old pointer value and the new allocated memory position (ofs), and then correct all affected pointers (+=ofs).

We rely on the fact that several variables (especially in AM) are already assigned the correct values by the startup functions. That means, in principle, that a change in the setup files between snapshot creation and recovery will be noticed.

Definition at line 1399 of file checkpoint.c.

Here is the call graph for this function:

4.5.3.8 DoCheckpoint()

```
void DoCheckpoint (
            int moduletype )
```

Checks whether a snapshot should be done. Calls DoSnapshot() to create the snapshot.

Definition at line 3102 of file checkpoint.c.

References PF_BroadcastNumber(), PF_RecvFile(), PF_SendFile(), and TimeWallClock().

Here is the call graph for this function:

4.5.4 Variable Documentation

4.5.4.1 cache_buffer

```
unsigned char cache_buffer[CACHE_SIZE]
```

Definition at line 1216 of file checkpoint.c.

4.5.4.2 cache_fill

```
size_t cache_fill = 0
```

Definition at line 1217 of file checkpoint.c.

4.7.1 Detailed Description

Compiler routines for statements that involve algebraic expressions. These involve definitions, id-statements, the multiply statement and the fill statement.

Definition in file comexpr.c.

4.7.2 Function Documentation

4.7.2.1 CoLocal()

```
int CoLocal (
            UBYTE * inp )
```

Definition at line 66 of file comexpr.c.

4.7.2.2 CoGlobal()

```
int CoGlobal (
            UBYTE * inp )
```

Definition at line 73 of file comexpr.c.

4.7.2.3 CoLocalFactorized()

```
int CoLocalFactorized (
            UBYTE * inp )
```

Definition at line 80 of file comexpr.c.

4.7.2.4 CoGlobalFactorized()

```
int CoGlobalFactorized (
            UBYTE * inp )
```

Definition at line 87 of file comexpr.c.

4.7.2.5 DoExpr()

```
int DoExpr (
            UBYTE * inp,
            int type,
            int par )
```

Definition at line 96 of file comexpr.c.

4.7.2.6 CoIdOld()

```
int CoIdOld (
            UBYTE * inp )
```

Definition at line 384 of file comexpr.c.

4.7.2.7 CoId()

```
int CoId (
            UBYTE * inp )
```

Definition at line 395 of file comexpr.c.

4.7.2.8 CoIdNew()

```
int CoIdNew (
            UBYTE * inp )
```

Definition at line 406 of file comexpr.c.

4.7.2.9 CoDisorder()

```
int CoDisorder (
            UBYTE * inp )
```

Definition at line 417 of file comexpr.c.

4.7.2.10 CoMany()

```
int CoMany (
            UBYTE * inp )
```

Definition at line 428 of file comexpr.c.

4.7.2.11 CoMulti()

```
int CoMulti (
            UBYTE * inp )
```

Definition at line 439 of file comexpr.c.

4.7.2.12 CoIfMatch()

```
int CoIfMatch (
            UBYTE * inp )
```

Definition at line 450 of file comexpr.c.

4.7.2.13 CoIfNoMatch()

```
int CoIfNoMatch (
            UBYTE * inp )
```

Definition at line 461 of file comexpr.c.

4.7.2.14 CoOnce()

```
int CoOnce (
            UBYTE * inp )
```

Definition at line 472 of file comexpr.c.

4.7.2.15 CoOnly()

```
int CoOnly (
            UBYTE * inp )
```

Definition at line 483 of file comexpr.c.

4.7.2.16 CoSelect()

```
int CoSelect (
            UBYTE * inp )
```

Definition at line 494 of file comexpr.c.

4.7.2.17 CoIdExpression()

```
int CoIdExpression (
            UBYTE * inp,
            int type )
```

Definition at line 507 of file comexpr.c.

4.7.2.18 CoMultiply()

```
int CoMultiply (
            UBYTE * inp )
```

Definition at line 1031 of file comexpr.c.

4.7.2.19 CoFill()

```
int CoFill (
            UBYTE * inp )
```

Definition at line 1070 of file comexpr.c.

4.7.2.20 CoFillExpression()

```
int CoFillExpression (
            UBYTE * inp )
```

Definition at line 1348 of file comexpr.c.

4.7.2.21 CoPrintTable()

```
int CoPrintTable (
            UBYTE * inp )
```

Definition at line 1734 of file comexpr.c.

4.7.2.22 CoAssign()

```
int CoAssign (
            UBYTE * inp )
```

Definition at line 1910 of file comexpr.c.

4.7.2.23 CoDeallocateTable()

```
int CoDeallocateTable (
            UBYTE * inp )
```

Definition at line 1968 of file comexpr.c.

    #] CoFill :
    #[ CoFillExpression :

    Syntax: FillExpression table = expression(x1,...,xn);
    The arguments should have been bracketed. Each corresponds to one
    of the dimensions of the table. Then the bracket with x1^2*x3^4
    will fill the (2,0,4) element of the table (if n=3 of course).
    Brackets that don't fit will be skipped. It just gives a warning.

    New option (13-jul-2005)
    Syntax: FillExpression table = expression(f);
    The table indices are arguments of the function f which should
    have been bracketed before.

4.9.1 Detailed Description

Compiler routines for most statements that don't involve algebraic expressions. Exceptions: all routines involving declarations are in the file names.c When making new statements one can add the compiler routines here and have a look whether there is already a routine that is similar. In that case one can make a copy and modify it.

Definition in file compcomm.c.

4.9.2 Function Documentation

4.9.2.1 CoCollect()

```
int CoCollect (
            UBYTE * s )
```

Definition at line 143 of file compcomm.c.

4.9.2.2 setonoff()

```
int setonoff (
            UBYTE * s,
            int * flag,
            int onvalue,
            int offvalue )
```

Definition at line 205 of file compcomm.c.

4.9.2.3 CoCompress()

```
int CoCompress (
            UBYTE * s )
```

Definition at line 221 of file compcomm.c.

4.9.2.4 CoFlags()

```
int CoFlags (
            UBYTE * s,
            int value )
```

Definition at line 270 of file compcomm.c.

4.9.2.5 CoOff()

```
int CoOff (
            UBYTE * s )
```

Definition at line 305 of file compcomm.c.

4.9.2.6 CoOn()

```
int CoOn (
            UBYTE * s )
```

Definition at line 362 of file compcomm.c.

4.9.2.7 CoInsideFirst()

```
int CoInsideFirst (
            UBYTE * s )
```

Definition at line 609 of file compcomm.c.

4.9.2.8 CoProperCount()

```
int CoProperCount (
            UBYTE * s )
```

Definition at line 616 of file compcomm.c.

4.9.2.9 CoDelete()

```
int CoDelete (
            UBYTE * s )
```

Definition at line 623 of file compcomm.c.

4.9.2.10 CoFormat()

```
int CoFormat (
            UBYTE * s )
```

Definition at line 668 of file compcomm.c.

4.9.2.11 CoKeep()

```
int CoKeep (
            UBYTE * s )
```

Definition at line 900 of file compcomm.c.

4.9.2.12 CoFixIndex()

```
int CoFixIndex (
            UBYTE * s )
```

Definition at line 912 of file compcomm.c.

4.9.2.13 CoMetric()

```
int CoMetric (
            UBYTE * s )
```

Definition at line 946 of file compcomm.c.

4.9.2.14 DoPrint()

```
int DoPrint (
            UBYTE * s,
            int par )
```

Definition at line 954 of file compcomm.c.

4.9.2.15 CoPrint()

```
int CoPrint (
            UBYTE * s )
```

Definition at line 1170 of file compcomm.c.

4.9.2.16 CoPrintB()

```
int CoPrintB (
            UBYTE * s )
```

Definition at line 1177 of file compcomm.c.

4.9.2.17 CoNPrint()

```
int CoNPrint (
            UBYTE * s )
```

Definition at line 1184 of file compcomm.c.

4.9.2.18 CoPushHide()

```
int CoPushHide (
            UBYTE * s )
```

Definition at line 1191 of file compcomm.c.

4.9.2.19 CoPopHide()

```
int CoPopHide (

```
int CoDropCoefficient (
            UBYTE * s )
```

Definition at line 5735 of file compcomm.c.

4.9.2.110 CoDropSymbols()

```
int CoDropSymbols (
            UBYTE * s )
```

Definition at line 5749 of file compcomm.c.

4.9.2.111 CoToPolynomial()

```
int CoToPolynomial (
            UBYTE * inp )
```

Definition at line 5772 of file compcomm.c.

4.9.2.112 CoFromPolynomial()

```
int CoFromPolynomial (
            UBYTE * inp )
```

Definition at line 5847 of file compcomm.c.

4.9.2.113 CoArgToExtraSymbol()

```
int CoArgToExtraSymbol (
            UBYTE * s )
```

Definition at line 5873 of file compcomm.c.

4.9.2.114 CoExtraSymbols()

```
int CoExtraSymbols (
            UBYTE * inp )
```

Definition at line 5923 of file compcomm.c.

4.9.2.115 GetIfDollarFactor()

```
WORD * GetIfDollarFactor (
            UBYTE ** inp,
            WORD * w )
```

Definition at line 5996 of file compcomm.c.

4.9.2.116 GetDoParam()

```
UBYTE * GetDoParam (
            UBYTE * inp,
            WORD ** wp,
            int par )
```

Definition at line 6054 of file compcomm.c.

4.9.2.117 CoDo()

```
int CoDo (
            UBYTE * inp )
```

Definition at line 6131 of file compcomm.c.

4.9.2.118 CoEndDo()

```
int CoEndDo (
            UBYTE * inp )
```

Definition at line 6234 of file compcomm.c.

4.9.2.119 CoFactDollar()

```
int CoFactDollar (
            UBYTE * inp )
```

Definition at line 6265 of file compcomm.c.

4.9.2.120 CoFactorize()

```
int CoFactorize (
            UBYTE * s )
```

Definition at line 6294 of file compcomm.c.

4.9.2.121 CoNFactorize()

```
int CoNFactorize (
            UBYTE * s )
```

Definition at line 6301 of file compcomm.c.

4.9.2.122 CoUnFactorize()

```
int CoUnFactorize (
            UBYTE * s )
```

Definition at line 6308 of file compcomm.c.

4.9.2.123 CoNUnFactorize()

```
int CoNUnFactorize (
            UBYTE * s )
```

Definition at line 6315 of file compcomm.c.

4.9.2.124 DoFactorize()

```
int DoFactorize (
            UBYTE * s,
            int par )
```

Definition at line 6322 of file compcomm.c.

4.9.2.125 CoOptimizeOption()

```
int CoOptimizeOption (
            UBYTE * s )
```

Definition at line 6455 of file compcomm.c.

4.9.2.126 CoPutInside()

```
int CoPutInside (
            UBYTE * inp )
```

Definition at line 6891 of file compcomm.c.

4.9.2.127 CoAntiPutInside()

```
int CoAntiPutInside (
            UBYTE * inp )
```

Definition at line 6892 of file compcomm.c.

4.11.1 Detailed Description

The heart of the compiler. It contains the tables of statements. It finds the statements in the tables and calls the proper routines. For algebraic expressions it runs the compilation by first calling the tokenizer, splitting things into subexpressions and generating the code. There is a system for recognizing already existing subexpressions. This economizes on the length of the output.

Note: the compiler of FORM doesn't attempt to normalize the input. Hence x+1 and 1+x are different objects during compilation. Similarly (a+b-b) will not be simplified to (a).

        #[ CodeGenerator :

        This routine does the real code generation.
        It returns the number of the rhs subexpression.
        At this point we do not have to worry about subexpressions,
        sets, setelements, simple vs complicated function arguments
        simple vs complicated powers etc.

        The variable 'first' indicates whether we are starting a new term

        The major complication are the set elements of type set[n].
        We have marked them as TSETNUM,n,Ttype,setnum
        They go into
        SETSET,size,subterm,relocation list
        in which the subterm should be ready to become a regular
        subterm in which the sets have been replaced by their element
        The relocation list consists of pairs of numbers:
        1: offset in the subterm, 2: the symbol n.
        Note that such a subterm can be a whole function with its arguments.
        We use the variable inset to indicate that we have something going.
        The relocation list is collected in the top of the WorkSpace.

/*
        #] CompleteTerm :
        #[ CodeFactors :

        This routine does the part of reading in in terms of factors.
        If there is more than one term at this level we have only one
        factor. In that case any expression should first be unfactorized.
        Then the whole expression gets read as a new subexpression and finally
        we generate factor_*subexpression.
        If the whole has only multiplications we have factors. Then the
        nasty thing is powers of objects and in particular powers of
        factorized expressions or dollars.
        For a power we generate a new subexpression of the type
          1+factor_+...+factor_^(power-1)
        with which we multiply.

        WE HAVE NOT YET WORRIED ABOUT SETS

00035
00036 #ifdef WITHZLIB
00037 /*
00038 #define GZIPDEBUG
00039
00040     Low level routines for dealing with zlib during sorting and handling
00041     the scratch files. Work started 5-sep-2005.
00042     The .sor file handling was more or less completed on 8-sep-2005
00043     The handling of the scratch files still needs some thinking.
00044     Complications are:
00045         gzip compression should be per expression, not per buffer.
00046         No gzip compression for expressions with a bracket index.
```

```
        Separate decompression buffers for expressions in the rhs.
        This last one will involve more buffer work and organization.
        Information about compression should be stored for each expr.
            (including what method/program was used)
    Note: Be careful with compression. By far the most compact method
    is the original problem....

    #[ Variables :

    The following variables are to contain the intermediate buffers
    for the inflation of the various patches in the sort file.
    There can be up to MaxFpatches (FilePatches in the setup) and hence
    we can have that many streams simultaneously. We set this up once
    and only when needed.
        (in struct A.N or AB[threadnum].N)
    Bytef **AN.ziobufnum;
    Bytef *AN.ziobuffers;

4.15.1 Detailed Description

Utility routines for the compiler.

Definition in file comtool.c.

4.15.2 Function Documentation

4.15.2.1 inicbufs()

```
int inicbufs (
            VOID  )
```

Creates a new compiler buffer and returns its ID number.

Returns

The ID number for the new compiler buffer.

Definition at line 47 of file comtool.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::BufferSize, CbUf::CanCommu, CbUf::dimension, CbUf::lhs, CbUf::numdum, CbUf::NumTerms, CbUf::Pointer, CbUf::rhs, and CbUf::Top.

Referenced by AddRHS(), and StartVariables().

4.15.2.2 finishcbuf()

```
void finishcbuf (
            WORD num )
```

Frees a compiler buffer.

Parameters

num	The ID number for the buffer to be freed.

Definition at line 89 of file comtool.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::BufferSize, CbUf::CanCommu, CbUf::lhs, CbUf::NumTerms, CbUf::Pointer, CbUf::rhs, and CbUf::Top.

Referenced by PF_BroadcastCBuf().

4.15.2.3 clearcbuf()

```
void clearcbuf (
            WORD num )
```

Clears contents in a compiler buffer.

Parameters

num	The ID number for the buffer to be cleared.

Definition at line 116 of file comtool.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::Pointer, and CbUf::rhs.

4.15.2.4 DoubleCbuffer()

```
WORD * DoubleCbuffer (
            int num,
            WORD * w,
            int par )
```

Doubles a compiler buffer.

Parameters

num	The ID number for the buffer to be doubled.
w	The pointer to the end (exclusive) of the current buffer. The contents in the range of [cbuf[num].Buffer,w) will be kept.

Definition at line 143 of file comtool.c.

References CbUf::Buffer, CbUf::BufferSize, CbUf::lhs, CbUf::Pointer, CbUf::rhs, and CbUf::Top.

Referenced by AddNtoC(), AddNtoL(), and TestSub().

4.15.2.5 AddLHS()

```
WORD * AddLHS (
            int num )
```

Adds an LHS to a compiler buffer and returns the pointer to a buffer for the new LHS.

Parameters

num	The ID number for the buffer to get another LHS.

Definition at line 188 of file comtool.c.

References CbUf::lhs, and CbUf::Pointer.

Referenced by AddNtoL().

4.15.2.6 AddRHS()

```
WORD * AddRHS (
            int num,
            int type )
```

Adds an RHS to a compiler buffer and returns the pointer to a buffer for the new RHS.

Parameters

num	The ID number for the buffer to get another RHS.
type	If 0, the subexpression tree will be reallocated.

Definition at line 214 of file comtool.c.

References TaBlEs::buffers, TaBlEs::buffersfill, TaBlEs::bufferssize, TaBlEs::bufnum, CbUf::CanCommu, CbUf::dimension, inicbufs(), CbUf::numdum, CbUf::NumTerms, CbUf::Pointer, and CbUf::rhs.

Referenced by InsertArg(), StartVariables(), TestMatch(), and TestSub().

Here is the call graph for this function:

4.15.2.7 AddNtoL()

```
int AddNtoL (
            int n,
            WORD * array )
```

Adds an LHS with the given data to the current compiler buffer.

Parameters

n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 288 of file comtool.c.

References AddLHS(), DoubleCbuffer(), CbUf::Pointer, and CbUf::Top.

Here is the call graph for this function:

4.15.2.8 AddNtoC()

```
int AddNtoC (
            int bufnum,
            int n,
            WORD * array,
            int par )
```

Adds the given data to the last LHS/RHS in a compiler buffer.

Parameters

bufnum	The ID number for the buffer where the data will be added.
n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 317 of file comtool.c.

References DoubleCbuffer(), CbUf::Pointer, and CbUf::Top.

Referenced by InsertArg(), and StartVariables().

Here is the call graph for this function:

4.15.2.9 InsTree()

```
int InsTree (
            int bufnum,
            int h )
```

Definition at line 355 of file comtool.c.

4.15.2.10 FindTree()

```
int FindTree (
            int bufnum,
            WORD * subexpr )
```

Definition at line 533 of file comtool.c.

4.15.2.11 RedoTree()

```
void RedoTree (
            CBUF * C,
            int size )
```

Definition at line 569 of file comtool.c.

4.15.2.12 ClearTree()

```
void ClearTree (
            int i )
```

Definition at line 588 of file comtool.c.

4.15.2.13 IniFbuffer()

```
int IniFbuffer (
            WORD bufnum )
```

Initialize a factorization cache buffer. We set the size of the rhs and boomlijst buffers immediately to their final values.

Definition at line 614 of file comtool.c.

References tree::blnce, CbUf::boomlijst, CbUf::CanCommu, CbUf::dimension, tree::left, CbUf::numdum, CbUf::NumTerms, tree::parent, CbUf::rhs, tree::right, tree::usage, and tree::value.

4.15.2.14 numcommute()

```
LONG numcommute (
            WORD * terms,
            LONG * numterms )
```

Definition at line 659 of file comtool.c.

4.16 comtool.c

    #] AddNtoC :
    #[ InsTree :

    Routines for balanced tree searching and insertion.
    Compared to Knuth we have a parent link. This minimizes the
    number of compares. That is better for anything that is more
    complicated than just single numbers.
    There are no provisions for removing elements from the tree.
    The routines are:
    void RedoTree(size) Re-allocates the tree space. There will
                        be MaxTreeSize = size elements.
    void ClearTree()    Prunes the tree down to the root element.
    int InsTree(int,int)Searches for the requested element. If not found it
                        will allocate a new element, balance the tree if
                        necessary and return the called number.
                        If it was in the tree, it returns the tree 'value'.

    Commentary: added the bufnum on 14-sep-2010 to make the whole a bit
    more flexible (JV).

4.19.1 Detailed Description

Contains macros and function declarations.

Definition in file declare.h.

4.19.2 Macro Definition Documentation

4.19.2.1 MaX

```
#define MaX(
            x,
            y ) ((x) > (y) ?  (x):  (y))
```

Definition at line 40 of file declare.h.

4.19.2.2 MiN

```
#define MiN(
            x,
            y ) ((x) < (y) ?  (x):  (y))
```

Definition at line 41 of file declare.h.

4.19.2.3 ABS

```
#define ABS(
            x ) ( (x) < 0 ?  -(x):  (x) )
```

Definition at line 42 of file declare.h.

4.19.2.4 SGN

```
#define SGN(
            x ) ( (x) > 0 ?  1 :  (x) < 0 ?  -1 :  0 )
```

Definition at line 43 of file declare.h.

4.19.2.5 REDLENG

```
#define REDLENG(
            x ) ((((x)<0)?((x)+1):((x)-1))/2)
```

Definition at line 44 of file declare.h.

4.19.2.6 INCLENG

```
#define INCLENG(
            x ) (((x)<0)?(((x)*2)-1):(((x)*2)+1))
```

Definition at line 45 of file declare.h.

4.19.2.7 GETCOEF

```
#define GETCOEF(
            x,
            y ) x += *x;y = x[-1];x -= ABS(y);y=REDLENG(y)
```

Definition at line 46 of file declare.h.

4.19.2.8 GETSTOP

```
#define GETSTOP(
            x,
            y ) y=x+(*x)-1;y -= ABS(*y)-1
```

Definition at line 47 of file declare.h.

4.19.2.9 StuffAdd

```
#define StuffAdd(
            x,
            y ) (((x)<0?-1:1)*(y)+((y)<0?-1:1)*(x))
```

Definition at line 48 of file declare.h.

4.19.2.10 EXCHN

```
#define EXCHN(
            t1,
            t2,
            n ) { WORD a,i; for(i=0;i<n;i++){a=t1[i];t1[i]=t2[i];t2[i]=a;} }
```

Definition at line 50 of file declare.h.

4.19.2.11 EXCH

```
#define EXCH(
            x,
            y ) { WORD a = (x); (x) = (y); (y) = a; }
```

Definition at line 51 of file declare.h.

4.19.2.12 TOKENTOLINE

```
#define TOKENTOLINE(
            x,
            y )
```

Value:

```
if ( AC.OutputSpaces == NOSPACEFORMAT ) { \
TokenToLine((UBYTE *)(y)); } else { TokenToLine((UBYTE *)(x)); }
```

Definition at line 53 of file declare.h.

4.19.2.13 UngetFromStream

```
#define UngetFromStream(
            stream,
            c ) ((stream)->nextchar[(stream)->isnextchar++]=c)
```

Definition at line 56 of file declare.h.

4.19.2.14 AddLineFeed

```
#define AddLineFeed(
            s,
            n ) { (s)[(n)++] = LINEFEED; }
```

Definition at line 60 of file declare.h.

4.19.2.15 TryRecover

```
#define TryRecover(
            x ) Terminate(-1)
```

Definition at line 62 of file declare.h.

4.19.2.16 UngetChar

```
#define UngetChar(
            c ) { pushbackchar = c; }
```

Definition at line 63 of file declare.h.

4.19.2.17 ParseNumber

```
#define ParseNumber(
            x,
            s ) {(x)=0;while(*(s)>='0'&&*(s)<='9')(x)=10*(x)+*(s)++ -'0';}
```

Definition at line 64 of file declare.h.

4.19.2.18 ParseSign

```
#define ParseSign(
            sgn,
            s )
```

Value:

```
{(sgn)=0;while(*(s)=='-'||*(s)=='+'){\
if ( *(s)++ == '-' ) sgn ^= 1;}}
```

Definition at line 65 of file declare.h.

4.19.2.19 ParseSignedNumber

```
#define ParseSignedNumber(
            x,
            s )
```

Value:

```
{ int sgn; ParseSign(sgn,s)\
ParseNumber(x,s) if ( sgn ) x = -x; }
```

Definition at line 67 of file declare.h.

4.19.2.20 NCOPY

```
#define NCOPY(
            s,
            t,
            n ) while ( --n >= 0 ) *s++ = *t++;
```

Definition at line 70 of file declare.h.

4.19.2.21 NCOPYI

```
#define NCOPYI(
            s,
            t,
            n ) while ( --n >= 0 ) *s++ = *t++;
```

Definition at line 73 of file declare.h.

4.19.2.22 NCOPYB

```
#define NCOPYB(
            s,
            t,
            n ) while ( --n >= 0 ) *s++ = *t++;
```

Definition at line 74 of file declare.h.

4.19.2.23 NCOPYI32

```
#define NCOPYI32(
            s,
            t,
            n ) while ( --n >= 0 ) *s++ = *t++;
```

Definition at line 75 of file declare.h.

4.19.2.24 WCOPY

```
#define WCOPY(
            s,
            t,
            n ) { int nn=n; WORD *ss=(WORD *)s, *tt=(WORD *)t; while ( --nn >= 0 ) *ss++=*tt++;
}
```

Definition at line 76 of file declare.h.

4.19.2.25 NeedNumber

```
#define NeedNumber(
            x,
            s,
            err )
```

Value:

```
        { int sgn = 1;                                  \
        while ( *s == ' ' || *s == '\t' || *s == '-' || *s == '+' ) {     \
            if ( *s == '-' ) sgn = -sgn; s++; }                           \
        if ( chartype[*s] != 1 ) goto err;                                \
        ParseNumber(x,s)                                                  \
        if ( sgn < 0 ) (x) = -(x); while ( *s == ' ' || *s == '\t' ) s++;\
    }
```

Definition at line 77 of file declare.h.

4.19.2.26 SKIPBLANKS

```
#define SKIPBLANKS(
            s ) { while ( *(s) == ' ' || *(s) == '\t' ) (s)++; }
```

Definition at line 84 of file declare.h.

4.19.2.27 FLUSHCONSOLE

```
#define FLUSHCONSOLE if ( AP.InOutBuf > 0 ) CharOut(LINEFEED)
```

Definition at line 85 of file declare.h.

4.19.2.28 SKIPBRA1

```

4.19.4 Function Documentation

4.19.4.1 TELLFILE()

```
VOID TELLFILE (
            int handle,
            POSITION * position )  [extern]
```

Definition at line 1334 of file tools.c.

4.19.4.2 StartVariables()

```
VOID StartVariables ( )  [extern]
```

All functions (well, nearly all) are declared here.

Definition at line 838 of file startup.c.

References AddNtoC(), AddRHS(), Compare1(), inicbufs(), FuNcTiOn::name, PF_BroadcastNumber(), PutPreVar(), and FuNcTiOn::symmetric.

Here is the call graph for this function:

4.19.4.3 CodeToLine()

```
UBYTE * CodeToLine (
            WORD number,
            UBYTE * Out )  [extern]
```

Definition at line 669 of file sch.c.

4.19.4.4 AddArrayIndex()

```
UBYTE * AddArrayIndex (
            WORD num,
            UBYTE * out )  [extern]
```

Definition at line 707 of file sch.c.

4.19.4.5 FindInIndex()

```
INDEXENTRY * FindInIndex (
            WORD expr,
            FILEDATA * f,
            WORD par,
            WORD mode )  [extern]
```

Definition at line 2644 of file store.c.

4.19.4.6 NextFileIndex()

```
INDEXENTRY * NextFileIndex (
            POSITION * indexpos )  [extern]
```

Definition at line 2237 of file store.c.

4.19.4.7 PasteTerm()

```
WORD * PasteTerm (
            PHEAD WORD number,
            WORD * accum,
            WORD * position,
            WORD times,
            WORD divby )  [extern]
```

Puts the term at position in the accumulator accum at position 'number+1'. if times $>$ 0 the coefficient of this term is multiplied by times/divby.

Parameters

number	The number of term fragments in accum that should be skipped
accum	The accumulator of term fragments
position	A position in (typically) a compiler buffer from where a (piece of a) term comes.
times	Multiply the result by this
divby	Divide the result by this.

This routine is typically used when we have to replace a (sub)expression pointer by a power of a (sub)expression. This uses mostly a binomial expansion and the new term is the old term multiplied one by one by terms of the new expression. The factors times and divby keep track of the binomial coefficient. Once this is complete, the routine FiniTerm will make the contents of the accumulator into a proper term that still needs to be normalized.

Definition at line 2808 of file proces.c.

Referenced by Generator().

4.19.4.8 StrCopy()

```
UBYTE * StrCopy (
            UBYTE * from,
            UBYTE * to )  [extern]
```

Definition at line 67 of file sch.c.

4.19.4.9 WrtPower()

```
UBYTE * WrtPower (
            UBYTE * Out,
            WORD Power )  [extern]
```

Definition at line 749 of file sch.c.

4.19.4.10 AccumGCD()

```
WORD AccumGCD (
            PHEAD UWORD * a,
            WORD * na,
            UWORD * b,
            WORD nb )  [extern]
```

Definition at line 647 of file reken.c.

4.19.4.11 AddArgs()

```
VOID AddArgs (
            PHEAD WORD * s1,
            WORD * s2,
            WORD * m )  [extern]
```

Adds the arguments of two occurrences of the PolyFun.

Parameters

s1	Pointer to the first occurrence.
s2	Pointer to the second occurrence.
m	Pointer to where the answer should be.

Definition at line 2250 of file sort.c.

Referenced by AddPoly(), and MergePatches().

4.19.4.12 AddCoef()

```
WORD AddCoef (
            PHEAD WORD ** ps1,
            WORD ** ps2 )  [extern]
```

Adds the coefficients of the terms ∗ps1 and ∗ps2. The problem comes when there is not enough space for a new longer coefficient. First a local solution is tried. If this is not succesfull we need to move terms around. The possibility of a garbage collection should not be ignored, as avoiding this costs very much extra space which is nearly wasted otherwise.

If the return value is zero the terms cancelled.

The resulting term is left in ∗ps1.

Definition at line 1961 of file sort.c.

References GarbHand(), and NormalModulus().

Referenced by SplitMerge().

Here is the call graph for this function:

4.19.4.13 AddLong()

```
WORD AddLong (
            UWORD * a,
            WORD na,
            UWORD * b,
            WORD nb,
            UWORD * c,
            WORD * nc )  [extern]
```

Definition at line 705 of file reken.c.

4.19.4.14 AddPLon()

```
WORD AddPLon (
            UWORD * a,
            WORD na,
            UWORD * b,
            WORD nb,
            UWORD * c,
            WORD * nc )  [extern]
```

Definition at line 750 of file reken.c.

4.19.4.15 AddPoly()

```
WORD AddPoly (
            PHEAD WORD ** ps1,
            WORD ** ps2 )  [extern]
```

Routine should be called when S->PolyWise != 0. It points then to the position of AR.PolyFun in both terms.

We add the contents of the arguments of the two polynomials. Special attention has to be given to special arguments. We have to reserve a space equal to the size of one term + the size of the argument of the other. The addition has to be done in this routine because not all objects are reentrant.

Newer addition (12-nov-2007). The PolyFun can have two arguments. In that case S->PolyFlag is 2 and we have to call the routine for adding rational polynomials. We have to be rather careful what happens with: The location of the output The order of the terms in the arguments At first we allow only univariate polynomials in the PolyFun. This restriction will be lifted a.s.a.p.

Parameters

ps1	A pointer to the postion of the first term
ps2	A pointer to the postion of the second term

Returns

If zero the terms cancel. Otherwise the new term is in ∗ps1.

Definition at line 2088 of file sort.c.

4.19.4.32 CompGroup()

```
WORD CompGroup (
            PHEAD WORD,
            WORD ** args,
            WORD * a1,
            WORD * a2,
            WORD num )  [extern]
```

Definition at line 373 of file function.c.

4.19.4.33 Compare1()

```
WORD Compare1 (
            WORD * term1,
            WORD * term2,
            WORD level )  [extern]
```

Compares two terms. The answer is: 0 equal (with exception of the coefficient if level == 0.) >0 term1 comes first. <0 term2 comes first. Some special precautions may be needed to keep the CompCoef routine from generating overflows, although this is very unlikely in subterms. This routine should not return an error condition.

Originally this routine was called Compare. With the treatment of special polynomials with terms that contain only symbols and the need for extreme speed for the polynomial routines we made a special compare routine and now we store the address of the current compare routine in AR.CompareRoutine and have a macro Compare which makes all existing code work properly and we can just replace the routine on a thread by thread basis (each thread has its own AR struct).

Parameters

term1	First input term
term2	Second input term
level	The sorting level (may influence on the result)

Returns

0 equal (with exception of the coefficient if level == 0.) >0 term1 comes first. <0 term2 comes first.

Definition at line 2535 of file sort.c.

Definition at line 1000 of file reshuf.c.

4.19.4.39 Deferred()

```
WORD Deferred (
            PHEAD WORD * term,
            WORD level )  [extern]
```

Picks up the deferred brackets. These are the bracket contents of which we postpone the reading when we use the 'Keep Brackets' statement. These contents are multiplying the terms just before they are sent to the sorting system. Special attention goes to having it thread-safe We have to lock positioning the file and reading it in a thread specific buffer.

Parameters

term	The term that must be multiplied by the contents of the current bracket
level	The compiler level. This is needed because after multiplying term by term we call Generator again.

Definition at line 4586 of file proces.c.

4.19.4.77 DoOnePow()

```
WORD DoOnePow (
            PHEAD WORD * term,
            WORD power,
            WORD nexp,
            WORD * accum,
            WORD * aa,
            WORD level,
            WORD * freeze )  [extern]
```

Routine gets one power of an expression in the scratch system. If there are more powers needed there will be a recursion.

No attempt is made to use binomials because we have no information about commutating properties.

There is a searching for the contents of brackets if needed. This searching may be rather slow because of the single links.

Parameters

term	is the term we are adding to.
power	is the power of the expression that we need.
nexp	is the number of the expression.
accum	is the accumulator of terms. It accepts the termfragments that are made into a proper term in FiniTerm
aa	points to the start of the entire accumulator. In ∗aa we store the number of term fragments that are in the accumulator.
level	is the current depth in the tree of statements. It is needed to continue to the next operation/substitution with each generated term
freeze	is the pointer to the bracket information that should be matched.

4.19.4.82 EndSort()

```
LONG EndSort (
            PHEAD WORD * buffer,
            int par )  [extern]
```

Finishes a sort. At AR.sLevel == 0 the output is to the regular output stream. When AR.sLevel $>$ 0, the parameter par determines the actual output. The AR.sLevel will be popped. All ongoing stages are finished and if the sortfile is open it is closed. The statistics are printed when AR.sLevel == 0 par == 0 Output to the buffer. par == 1 Sort for function arguments. The output will be copied into the buffer. It is assumed that this is in the WorkSpace. par == 2 Sort for $-variable. We return the address of the buffer that contains the output in buffer (treated like WORD $**$). We first catch the output in a file (unless we can intercept things after the small buffer has been sorted) Then we read from the file into a buffer. Only when par == 0 data compression can be attempted at AT.SS==AT.S0.

Parameters

buffer	buffer for output when needed
par	See above

Returns

If negative: error. If positive: number of words in output.

            WORD number,
            WORD tepos )  [extern]
```

Concatenates the contents of the accumulator into a single legal term, which replaces the subexpression pointer

Parameters

term	the input term with the (sub)expression subterm
accum	the accumulator with the term fragments
termout	the location where the output should be written
number	the number of term fragments in the accumulator
tepos	the position of the subterm in term to be replaced

WORD FlushOut (
```

```
            POSITION * position,
            FILEHANDLE * fi,
            int compr )  [extern]
```

Completes output to an output file and writes the trailing zero.

Parameters

position	The position in the file after writing
fi	The file (or its cache)
compr	Indicates whether there should be compression with gzip.

Returns

Regular conventions (OK -> 0).

4.19.4.104 Generator()

```
WORD Generator (
            PHEAD WORD * term,
            WORD level )  [extern]
```

The heart of the program. Here the expansion tree is set up in one giant recursion

Parameters

term	the input term. may be overwritten
level	the level in the compiler buffer (number of statement)

Returns

Normal conventions (OK = 0).

The routine looks first whether there are unsubstituted (sub)expressions. If so, one of them gets inserted term by term and the new term is used in a renewed call to Generator. If there are no (sub)expressions, the term is normalized, the compiler level is raised (next statement) and the program looks what type of statement this is. If this is a special statement it is either treated on the spot or the appropriate routine is called. If it is a substitution, the pattern matcher is called (TestMatch) which tells whether there was a match. If so we need to call TestSub again to test for (sub)expressions. If we run out of levels, the term receives a final treatment for modulus calculus and/or brackets and is then sent off to the sorting routines.

```
WORD InFunction (
            PHEAD WORD * term,
            WORD * termout )  [extern]
```

Makes the replacement of the subexpression with the number 'replac' in a function argument. Additional information is passed in some of the AR, AN, AT variables.

Parameters

term	The input term
termout	The output term

Returns

0: everything is fine, Negative: fatal, Positive: error.

Special attention should be given to nested functions!

Definition at line 2004 of file proces.c.

References Compare1(), CompareSymbols(), EndSort(), Generator(), LowerSortLevel(), NewSort(), StoreTerm(), and SymbolNormalize().

            WORD * position,
            WORD * termout,
            WORD tepos )  [extern]
```

Puts the terms 'term' and 'position' together into a single legal term in termout. replac is the number of the subexpression that should be replaced. It must be a positive term. When action is needed in the argument of a function all terms in that argument are dealt with recursively. The subexpression is sorted. Only one subexpression is done at a time this way.

Parameters

term	the input term
replac	number of the subexpression pointer to replace
extractbuff	number of the compiler buffer replac refers to
position	position from where to take the term in the compiler buffer
termout	the output term
tepos	offset in term where the subexpression is.

Returns

Normal conventions (OK = 0).

4.19.4.128 MergePatches()

```
WORD MergePatches (
            WORD par )  [extern]
```

The general merge routine. Can be used for the large buffer and the file merging. The array S->Patches tells where the patches start S->pStop tells where they end (has to be computed first). The end of a 'line to be merged' is indicated by a zero. If the end is reached without running into a zero or a term runs over the boundary of a patch it is a file merging operation and a new piece from the file is read in.

Parameters

par	If par == 0 the sort is for file -> outputfile. If par == 1 the sort is for large buffer -> sortfile. If par == 2 the sort is for large buffer -> outputfile.

Definition at line 3576 of file sort.c.

4.19.4.145 PasteFile()

```
LONG PasteFile (
            PHEAD WORD number,
            WORD * accum,
            POSITION * position,
            WORD ** accfill,
            RENUMBER renumber,
            WORD * freeze,
            WORD nexpr )  [extern]
```

Gets a term from stored expression expr and puts it in the accumulator at position number. It returns the length of the term that came from file.

Parameters

number	number of partial terms to skip in accum
accum	the accumulator
position	file position from where to get the stored term
accfill	returns tail position in accum
renumber	the renumber struct for the variables in the stored expression
freeze	information about if we need only the contents of a bracket
nexpr	the number of the stored expression

Returns

Normal conventions (OK = 0).

Definition at line 2686 of file proces.c.

Referenced by Generator().

4.19.4.148 PolyFunMul()

```
WORD PolyFunMul (
            PHEAD WORD * term )  [extern]
```

Multiplies the arguments of multiple occurrences of the polyfun. In this routine we do the original PolyFun with one argument only. The PolyRatFun (PolyFunType = 2) is done in a dedicated routine in the file polywrap.cc The new result is written over the old result.

Parameters

term	It contains the input term and later the output.

Returns

Normal conventions (OK = 0).

Definition at line 5102 of file proces.c.

References EndSort(), LowerSortLevel(), NewSort(), and StoreTerm().

Referenced by Generator().

Here is the call graph for this function:

4.19.4.149 PrepPoly()

```
WORD PrepPoly (
            PHEAD WORD * term,
            WORD par )  [extern]
```

Routine checks whether the count of function AR.PolyFun is zero or one. If it is one and it has one scalarlike argument the coefficient of the term is pulled inside the argument. If the count is zero a new function is made with the coefficient as its only argument. The function should be placed at its proper position.

When this function is active it places the PolyFun as last object before the coefficient. This is needed because otherwise the compress algorithm has problems in MergePatches.

The bracket routine should also place the PolyFun at a comparable spot. The compression should then stop at the PolyFun. It doesn't really have to stop when writing the final result but this may be too complicated.

The parameter par tells whether we are at groundlevel or inside a function or dollar variable.

Definition at line 4714 of file proces.c.

            PHEAD WORD * termin )  [extern]
```

Definition at line 1063 of file execute.c.

4.19.4.153 PutIn()

```
LONG PutIn (
            FILEHANDLE * file,
            POSITION * position,
            WORD * buffer,
            WORD ** take,
            int npat )  [extern]
```

Reads a new patch from position in file handle. It is put at buffer, anything after take is moved forward. This would be part of a term that hasn't been used yet. Because of this there should be some space before the start of the buffer

Parameters

file	The file system from which to read
position	The position from which to read
buffer	The buffer into which to read
take	The unused tail should be moved before the buffer
npat	The number of the patch. Is needed if the information was compressed with gzip, because each patch has its own independent gzip encoding.

Definition at line 1258 of file sort.c.

References FiLe::handle.

Referenced by MergePatches().

4.19.4.154 PutInStore()

```
WORD PutInStore (
            INDEXENTRY * ind,
            WORD num )  [extern]
```

Definition at line 861 of file store.c.

4.19.4.155 PutOut()

```
WORD PutOut (
            PHEAD WORD * term,
            POSITION * position,
            FILEHANDLE * fi,
            WORD ncomp )  [extern]
```

Routine writes one term to file handle at position. It returns the new value of the position.

NOTE: For 'final output' we may have to index the brackets. See the struct BRACKETINDEX. We should maintain: 1: a list with brackets array with the brackets 2: a list of objects of type BRACKETINDEX. It contains array with either pointers or offsets to the list of brackets. starting positions in the file. The index may be tied to a maximum size. In that case we may have to prune the list occasionally.

Parameters

term	The term to be written
position	The position in the file. Afterwards it is updated
fi	The file (or its cache) to which should be written
ncomp	Information about what type of compression should be used

Definition at line 1404 of file sort.c.

```
WORD RaisPow (
            PHEAD UWORD * a,
            WORD * na,
            UWORD b )  [extern]
```

Definition at line 1218 of file reken.c.

4.19.4.158 RaisPowCached()

```
VOID RaisPowCached (
            PHEAD WORD x,
            WORD n,
            UWORD ** c,
            WORD * nc )  [extern]
```

Computes power x^n and caches the value

4.19.5 Description

Calculates the power x^n and stores the results for caching purposes. The pointer c (i.e., the pointer, and not what it points to) is overwritten. What it points to should not be overwritten in the calling function.

4.19.6 Notes

- Caching is done in AT.small_power[]. This array is extended if necessary.

Definition at line 1286 of file reken.c.

4.19.6.1 RaisPowMod()

```
WORD RaisPowMod (
            WORD x,
            WORD n,
            WORD m )  [extern]
```

Definition at line 1373 of file reken.c.

4.19.6.2 NormalModulus()

```
int NormalModulus (
            UWORD * a,
            WORD * na )  [extern]
```

Brings a modular representation in the range -p/2 to +p/2 The return value tells whether anything was done. Routine made in the general modulus revamp of July 2008 (JV).

Definition at line 1393 of file reken.c.

Referenced by AddCoef(), and MergePatches().

4.19.6.3 GetModInverses()

```
int GetModInverses (
            WORD m1,
            WORD m2,
            WORD * im1,
            WORD * im2 )  [extern]
```

Input m1 and m2, which are relative prime. determines a∗m1+b∗m2 = 1 (and 1 is the gcd of m1 and m2) then a∗m1 = 1 mod m2 and hence im1 = a. and b∗m2 = 1 mod m1 and hence im2 = b. Set m1 = 0∗m1+1∗m2 = a1∗m1+b1∗m2 m2 = 1∗m1+0∗m2 = a2∗m1+b2∗m2 If everything is OK, the return value is zero

4.19.6.21 SplitMerge()

```
LONG SplitMerge (
            PHEAD WORD ** Pointer,
            LONG number )  [extern]
```

Algorithm by J.A.M.Vermaseren (31-7-1988)

Note that AN.SplitScratch and AN.InScratch are used also in GarbHand

Merge sort in memory. The input is an array of pointers. Sorting is done recursively by dividing the array in two equal parts and calling SplitMerge for each. When the parts are small enough we can do the compare and take the appropriate action. An addition is that we look for 'runs'. Sequences that are already ordered. This happens a lot when there is very little action in a module. This made FORM faster by a few percent.

Parameters

Pointer	The array of pointers to the terms to be sorted.
number	The number of pointers in Pointer.

The terms are supposed to be sitting in the small buffer and there is supposed to be an extension to this buffer for

when there are two terms that should be added and the result takes more space than each of the original terms. The notation guarantees that the result never needs more space than the sum of the spaces of the original terms.

Definition at line 552 of file execute.c.

4.19.6.36 TestMatch()

```
WORD TestMatch (
            PHEAD WORD * term,
            WORD * level )  [extern]
```

This routine governs the pattern matching. If it decides that a substitution should be made, this can be either the insertion of a right hand side (C->rhs) or the automatic generation of terms as a result of an operation (like trace). The object to be replaced is removed from term and a subexpression pointer is inserted. If the substitution is made more than once there can be more subexpression pointers. Its number is positive as it corresponds to the level at which the C->rhs can be found in the compiler output. The subexpression pointer contains the wildcard substitution information. The power is found in ∗AT.TMout. For operations the subexpression pointer is negative and corresponds to an address in the array AT.TMout. In this array are then the instructions for the routine to be called and its number in the array 'Operations' The format is here: length,functionnumber,length-2 parameters

There is a certain complexity wrt repeat levels. Another complication is the poking of the wildcard values in the subexpression prototype in the compiler buffer. This was how things were done in the past with sequential FORM, but with the advent of TFORM this cannot be maintained. Now, for TFORM we make a copy of it. 7-may-2008 (JV): We cannot yet guarantee that this has been done 100% correctly. There are errors that occur in TFORM only and that may indicate problems.

Definition at line 97 of file pattern.c.

Here is the call graph for this function:

4.19.6.37 TestSub()

```
WORD TestSub (
            PHEAD WORD * term,
            WORD level )  [extern]
```

TestSub hunts for subexpression pointers. If one is found its power is given in AN.TeSuOut. and the returnvalue is 'expressionnumber'. If the expression number is negative it is an expression on disk.

In addition this routine tries to locate subexpression pointers in functions. It also notices that action must be taken with any of the special functions.

Parameters

term	The term in which TestSub hunts for potential action
level	The number of the 'level' in the compiler buffer.

Returns

The number of the (sub)expression that was encountered.

Other values that are returned are in AN.TeSuOut, AR.TePos, AT.TMbuff, AN.TeInFun, AN.Frozen, AT.TMaddr

The level in the compiler buffer is more or less the number of the statement in the module. Hence it refers to the element in the lhs array.

This routine is one of the most important routines in FORM.

Definition at line 3460 of file tools.c.

4.19.6.40 TimeWallClock()

```
LONG TimeWallClock (
            WORD par )  [extern]
```

Returns the wall-clock time.

Parameters

par	If zero, the wall-clock time will be reset to 0.

Returns

The wall-clock time in centiseconds.

Definition at line 3404 of file tools.c.

Referenced by DoCheckpoint(), DoRecovery(), and WriteStats().

4.19.6.60 WriteStats()

```
VOID WriteStats (
            POSITION * plspace,
            WORD par )  [extern]
```

Writes the statistics.

Parameters

plspace	The size in bytes currently occupied
par	par = 0 after a splitmerge. par = 1 after merge to sortfile. par = 2 after the sort

current expression is to be found in AR.CurExpr. terms are in S->TermsLeft. S->GenTerms.

Definition at line 93 of file sort.c.

            UBYTE * value,
            UBYTE * args,
            int mode )  [extern]
```

Inserts/Updates a preprocessor variable in the name administration.

Parameters

name	Character string with the variable name.
value	Character string with a possible value. Special case: if this argument is zero, then we have no value. Note: This is different from having an empty argument! This should only occur when the name starts with a ?
args	Character string with possible arguments.
mode	=0: always create a new name entry, =1: try to do a redefinition if possible.

Returns

Index of used entry in name list.

```
int CopyFile (
            char * source,
            char * dest )  [extern]
```

Copies a file with name ∗source to a file named ∗dest. The involved files must not be open. Returns non-zero if an error occurred. Uses if possible the combined large and small sorting buffers as cache.

Definition at line 1029 of file tools.c.

```
int TheDefine (
            UBYTE * s,
            int mode )  [extern]
```

Preprocessor assignment. Possible arguments and values are treated and the new preprocessor variable is put into the name administration.

Parameters

s	Pointer to the character string following the preprocessor command.
mode	Bitmask. 0-bit clear: always create a new name entry, 0-bit set: try to redefine an existing name, 1-bit set: ignore preprocessor if/switch status.

Returns

zero: no errors, negative number: errors.

Definition at line 1942 of file pre.c.

4.19.6.275 ComPress()

```
LONG ComPress (
            WORD ** ss,
            LONG * n )  [extern]
```

Gets a list of pointers to terms and compresses the terms. In n it collects the number of terms and the return value of the function is the space that is occupied.

We have to pay some special attention to the compression of terms with a PolyFun. This PolyFun should occur only straight before the coefficient, so we can use the same trick as for the coefficient to sabotage compression of this object (Replace in the history the function pointer by zero. This is safe, because terms that would be identical otherwise would have been added).

Parameters

ss	Array of pointers to terms to be compressed.
n	Number of pointers in ss.

Returns

Total number of words needed for the compressed result.

Definition at line 3073 of file sort.c.

Referenced by EndSort(), and StoreTerm().

4.19.6.276 StageSort()

```
VOID StageSort (
            FILEHANDLE * fout )  [extern]
```

Prepares a stage 4 or higher sort. Stage 4 sorts occur when the sort file contains more patches than can be merged in one pass.

Definition at line 4452 of file sort.c.

References FiLe::handle.

Referenced by EndSort(), and MergePatches().

4.19.6.285 DoubleCbuffer()

```
WORD * DoubleCbuffer (
            int num,
            WORD * w,
            int par )  [extern]
```

Doubles a compiler buffer.

Parameters

num	The ID number for the buffer to be doubled.
w	The pointer to the end (exclusive) of the current buffer. The contents in the range of [cbuf[num].Buffer,w) will be kept.

Definition at line 143 of file comtool.c.

References CbUf::Buffer, CbUf::BufferSize, CbUf::lhs, CbUf::Pointer, CbUf::rhs, and CbUf::Top.

4.19.6.286 AddLHS()

```
WORD * AddLHS (
            int num )  [extern]
```

Adds an LHS to a compiler buffer and returns the pointer to a buffer for the new LHS.

Parameters

num	The ID number for the buffer to get another LHS.

Definition at line 188 of file comtool.c.

References CbUf::lhs, and CbUf::Pointer.

Referenced by AddNtoL().

4.19.6.287 AddRHS()

```
WORD * AddRHS (
            int num,
            int type )  [extern]
```

Adds an RHS to a compiler buffer and returns the pointer to a buffer for the new RHS.

Parameters

num	The ID number for the buffer to get another RHS.
type	If 0, the subexpression tree will be reallocated.

Definition at line 214 of file comtool.c.

References TaBlEs::buffers, TaBlEs::buffersfill, TaBlEs::bufferssize, TaBlEs::bufnum, CbUf::CanCommu, CbUf::dimension, inicbufs(), CbUf::numdum, CbUf::NumTerms, CbUf::Pointer, and CbUf::rhs.

4.19.6.288 AddNtoL()

```
int AddNtoL (
            int n,
            WORD * array )  [extern]
```

Adds an LHS with the given data to the current compiler buffer.

Parameters

n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 288 of file comtool.c.

References AddLHS(), DoubleCbuffer(), CbUf::Pointer, and CbUf::Top.

Here is the call graph for this function:

4.19.6.289 AddNtoC()

```

Definition at line 1759 of file compcomm.c.

4.19.6.298 ArgFactorize()

```
int ArgFactorize (
            PHEAD WORD * argin,
            WORD * argout )  [extern]
```

Definition at line 2015 of file argument.c.

4.19.6.299 TakeArgContent()

```
WORD * TakeArgContent (
            PHEAD WORD * argin,
            WORD * argout )  [extern]
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. The common pieces are put in argout as a sequence of arguments. The part with the multiple terms that are now relative prime is put in argfree which is allocated via TermMalloc and is given as the return value. The difference with the old code is that negative powers are always removed. Hence it is as in MakeInteger in which only numerators will be left: now only zero or positive powers will be remaining.

Definition at line 2716 of file argument.c.

References EndSort(), MakeInteger(), MakeMod(), NewSort(), and StoreTerm().

Here is the call graph for this function:

4.19.6.300 MakeInteger()

```
WORD * MakeInteger (
            PHEAD WORD * argin,
            WORD * argout,
            WORD * argfree )  [extern]
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in argin. The number that comes out should go to argout. The new pointer in the argout buffer is the return value. The normalized argument is in argfree.

Definition at line 3262 of file argument.c.

Referenced by TakeArgContent().

4.19.6.301 MakeMod()

```
WORD * MakeMod (
            PHEAD WORD * argin,
            WORD * argout,
            WORD * argfree )  [extern]
```

Similar to MakeInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3433 of file argument.c.

References GetModInverses().

Referenced by TakeArgContent().

Here is the call graph for this function:

4.19.6.302 FindArg()

```
WORD FindArg (
            PHEAD WORD * a )  [extern]
```

Looks the argument up in the (workers) table. If it is found the number in the table is returned (plus one to make it positive). If it is not found we look in the compiler provided table. If it is found - the number in the table is returned (minus one to make it negative). If in neither table we return zero.

Definition at line 2463 of file argument.c.

4.19.6.303 InsertArg()

```
WORD InsertArg (
            PHEAD WORD * argin,
            WORD * argout,
            int par )  [extern]
```

Inserts the argument into the (workers) table. If the table is too full we eliminate half of it. The eliminated elements are the ones that have not been used most recently, weighted by their total use and age(?). If par == 0 it inserts in the regular factorization cache If par == 1 it inserts in the cache defined with the FactorCache statement

Definition at line 2487 of file argument.c.

References AddNtoC(), AddRHS(), and CleanupArgCache().

Here is the call graph for this function:

4.19.6.304 CleanupArgCache()

```
int CleanupArgCache (
            PHEAD WORD bufnum )  [extern]
```

Cleans up the argument factorization cache. We throw half the elements. For a weight of what we want to keep we use the product of usage and the number in the buffer.

Definition at line 2522 of file argument.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::Pointer, CbUf::rhs, SortWeights(), and tree::usage.

            UBYTE * inp )  [extern]
```

Definition at line 1968 of file comexpr.c.

4.19.6.532 CleanDollarFactors()

```
void CleanDollarFactors (
            DOLLARS d )  [extern]
```

Definition at line 3549 of file dollar.c.

4.19.6.533 TakeDollarContent()

```
WORD * TakeDollarContent (
            PHEAD WORD * dollarbuffer,
            WORD ** factor )  [extern]
```

Definition at line 3570 of file dollar.c.

4.19.6.534 MakeDollarInteger()

```
WORD * MakeDollarInteger (
            PHEAD WORD * bufin,
            WORD ** bufout )  [extern]
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in bufin. The number that comes out is the return value. The normalized argument is in bufout.

Definition at line 3622 of file dollar.c.

References EndSort(), Generator(), and NewSort().

Here is the call graph for this function:

4.19.6.535 MakeDollarMod()

```
WORD * MakeDollarMod (
            PHEAD WORD * buffer,
            WORD ** bufout )  [extern]
```

Similar to MakeDollarInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3796 of file dollar.c.

References EndSort(), Generator(), GetModInverses(), and NewSort().

Here is the call graph for this function:

4.19.6.536 GetDolNum()

```
int GetDolNum (
            PHEAD WORD * t,
            WORD * tstop )  [extern]
```

Definition at line 3841 of file dollar.c.

4.19.6.537 AddPotModdollar()

```
void AddPotModdollar (
            WORD numdollar )  [extern]
```

Adds a $-variable specified by *numdollar* to the list of potentially modified $-variables unless it has already been included in the list.

Parameters

numdollar	The index of the $-variable to be added.

Definition at line 3954 of file dollar.c.

4.19.6.538 TakeLongRoot()

```
int TakeLongRoot (
            UWORD * a,

Definition at line 288 of file tables.c.

4.19.6.546 finishcbuf()

```
void finishcbuf (
            WORD num )  [extern]
```

Frees a compiler buffer.

Parameters

num	The ID number for the buffer to be freed.

Definition at line 89 of file comtool.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::BufferSize, CbUf::CanCommu, CbUf::lhs, CbUf::NumTerms, CbUf::Pointer, CbUf::rhs, and CbUf::Top.

Referenced by PF_BroadcastCBuf().

4.19.6.547 clearcbuf()

```
void clearcbuf (
            WORD num )  [extern]
```

Clears contents in a compiler buffer.

Parameters

num	The ID number for the buffer to be cleared.

Definition at line 116 of file comtool.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::Pointer, and CbUf::rhs.

4.19.6.548 CleanUpSort()

```
void CleanUpSort (
            int num )  [extern]
```

Partially or completely frees function sort buffers.

Definition at line 4643 of file sort.c.

4.19.6.549 AllocFileHandle()

```
FILEHANDLE * AllocFileHandle (
            WORD par,

```

Definition at line 4891 of file sort.c.

4.19.6.555 InsideDollar()

```
int InsideDollar (
            PHEAD WORD * ll,
            WORD level )  [extern]
```

Definition at line 1750 of file dollar.c.

4.19.6.556 DolToTerms()

```
DOLLARS DolToTerms (
            PHEAD WORD )  [extern]
```

Definition at line 1462 of file dollar.c.

4.19.6.557 EvalDoLoopArg()

```
WORD EvalDoLoopArg (
            PHEAD WORD * arg,
            WORD par )  [extern]
```

Evaluates one argument of a do loop. Such an argument is constructed from SNUMBERs DOLLAREXPRESSIONs and possibly DOLLAREXPR2s which indicate factors of the preceeding dollar. Hence we have SNUMBER,num DOLLAREXPRESSION,numdollar DOLLAREXPRESSION,numdollar,DOLLAREXPR2,numfactor DOLLAREXPRESSION,numdollar,DOLLAREXPR2,numfactor,DOLLAREXPR2,numfactor etc. Because we have a do-loop at every stage we should have a number. The notation in DOLLAREXPR2 is that $>=$ 0 is number of yet another dollar and $<$ 0 is -n-1 with n the array element or zero. The return value is the (short) number. The routine works its way through the list in a recursive manner.

Definition at line 2646 of file dollar.c.

Definition at line 5875 of file pre.c.

4.19.6.642 SymbolNormalize()

```
int SymbolNormalize (
            WORD * term )  [extern]
```

Routine normalizes terms that contain only symbols. Regular minimum and maximum properties are ignored.

We check whether there are negative powers in the output. This is not allowed.

Definition at line 5000 of file normal.c.

Referenced by InFunction().

4.19.6.643 TestFunFlag()

```
int TestFunFlag (
            PHEAD WORD * tfun )  [extern]
```

Definition at line 5096 of file normal.c.

4.19.6.644 CompareSymbols()

```
WORD CompareSymbols (
            WORD * term1,
            WORD * term2,
            WORD par )  [extern]
```

Compares the terms, based on the value of AN.polysortflag. If term1 < term2 the return value is -1 If term1 > term2 the return value is 1 If term1 = term2 the return value is 0 The coefficients may differ. The terms contain only a single subterm of type SYMBOL. If AN.polysortflag = 0 it is a 'regular' compare. If AN.polysortflag = 1 the sum of the powers is more important par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in sort.c

Definition at line 2975 of file sort.c.

Referenced by InFunction(), and TestSub().

4.19.6.645 CompareHSymbols()

```
WORD CompareHSymbols (
            WORD * term1,
            WORD * term2,
            WORD par )  [extern]
```

Compares terms that can have only SYMBOL and HAAKJE subterms. If term1 < term2 the return value is -1 If term1 > term2 the return value is 1 If term1 = term2 the return value is 0 par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in sort.c

Definition at line 3019 of file sort.c.

4.19.6.646 NextPrime()

```
WORD NextPrime (
            PHEAD WORD num )  [extern]
```

Gives the next prime number in the list of prime numbers.

If the list isn't long enough we expand it. For ease in ParForm and because these lists shouldn't be very big we let each worker keep its own list.

The list is cut off at MAXPOWER, because we don't want to get into trouble that the power of a variable gets larger than the prime number.

Definition at line 3654 of file reken.c.

            PHEAD WORD * prf )  [extern]
```

Definition at line 4816 of file normal.c.

4.19.6.652 ReadSaveIndex()

```
WORD ReadSaveIndex (
            FILEINDEX * fileind )  [extern]
```

Reads a FILEINDEX from the open save file specified by AO.SaveData.Handle. Translations for adjusting endianness and data sizes are done if necessary.

Depends on the assumption that sizeof(FILEINDEX) is the same everywhere. If FILEINDEX or INDEXENTRY change, then this functions has to be adjusted.

Called by CoLoad() and FindInIndex().

Parameters

fileind	contains the read FILEINDEX after succesful return. must point to allocated, big enough memory.

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4137 of file store.c.

References INFILEINDEX, FiLeInDeX::next, FiLeInDeX::number, and FuNcTiOn::number.

4.19.6.653 ReadSaveExpression()

```
WORD ReadSaveExpression (
            UBYTE * buffer,
            UBYTE * top,
            LONG * size,
            LONG * outsize )  [extern]
```

Reads an expression from the open file specified by AO.SaveData.Handle. The endianness flip and a resizing without renumbering is done in this function. Thereafter the buffer consists of chunks with a uniform maximal word size (32bit at the moment). The actual renumbering is then done by calling the function ReadSaveTerm32(). The result is returned in *buffer*.

If the translation at some point doesn't fit into the buffer anymore, the function returns and must be called again. In any case *size* returns the number of successfully read bytes, *outsize* returns the number of successfully written bytes, and the file will be positioned at the next byte after the successfully read data.

It is called by PutInStore().

Parameters

buffer	output buffer, holds the (translated) expression
top	end of buffer
size	number of read bytes
outsize	number of written bytes

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 5092 of file store.c.

References ReadSaveTerm32().

Here is the call graph for this function:

4.19.6.654 ReadSaveTerm32()

```
UBYTE * ReadSaveTerm32 (
            UBYTE * bin,
            UBYTE * binend,
            UBYTE ** bout,
            UBYTE * boutend,
            UBYTE * top,
            int terminbuf )  [extern]
```

Reads a single term from the given buffer at *bin* and write the translated term back to this buffer at *bout*.

ReadSaveTerm32() is currently the only instantiation of a ReadSaveTerm-function. It only deals with data that already has the correct endianness and that is resized to 32bit words but without being renumbered or translated in any other way. It uses the compress buffer AR.CompressBuffer.

The function is reentrant in order to cope with nested function arguments. It is called by ReadSaveExpression() and itself.

The *return value* indicates the position in the input buffer up to which the data has already been successfully processed. The parameter *bout* returns the corresponding position in the output buffer.

Parameters

bin	start of the input buffer
binend	end of the input buffer
bout	as input points to the beginning of the output buffer, as output points behind the already translated data in the output buffer
boutend	end of already decompressed data in output buffer
top	end of output buffer
terminbuf	flag whether decompressed data is already in the output buffer. used in recursive calls

Returns

pointer to the next unprocessed data in the input buffer

Definition at line 4683 of file store.c.

References ReadSaveTerm32().

Referenced by ReadSaveExpression(), and ReadSaveTerm32().

Here is the call graph for this function:

4.19.6.655 ReadSaveVariables()

```
WORD ReadSaveVariables (
            UBYTE * buffer,
            UBYTE * top,
            LONG * size,
            LONG * outsize,
            INDEXENTRY * ind,
            LONG * stage )  [extern]
```

Reads the variables from the open file specified by AO.SaveData.Handle. It reads the ∗size bytes and writes them to the ∗buffer. It is called by PutInStore().

If translation is necessary, the data might shrink or grow in size, then ∗*size* is adjusted so that the reading and writing fits into the memory from the buffer to the top. The actual number of read bytes is returned in ∗*size*, the number of written bytes is returned in ∗*outsize*.

If the ∗size is smaller than the actual size of the variables, this function will be called several times and needs to remember the current position in the variable structure. The parameter *stage* does this job. When ReadSaveVariables() is called for the first time, this parameter should have the value -1.

The parameter *ind* is used to get the number of variables.

Parameters

buffer	read variables are written into this allocated memory
top	upper end of allocated memory
size	number of bytes to read. might return a smaller number of read bytes if translation was necessary
outsize	if translation has be done, outsize contains the number of written bytes
ind	pointer of INDEXENTRY for the current expression. read-only
stage	should be -1 for the first call, will be increased by ReadSaveVariables to memorize the position in the variable structure

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4323 of file store.c.

References InDeXeNtRy::nfunctions, InDeXeNtRy::nindices, InDeXeNtRy::nsymbols, InDeXeNtRy::nvectors, and FuNcTiOn::spec.

4.19.6.656 WriteStoreHeader()

```
WORD WriteStoreHeader (
            WORD handle )  [extern]
```

Writes header with information about system architecture and FORM revision to an open store file.

Called by SetFileIndex().

Parameters

handle	specifies open file to which header will be written

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 3926 of file store.c.

References STOREHEADER::endianness, STOREHEADER::lenLONG, STOREHEADER::lenPOINTER, STOREHEADER::lenPOS, STOREHEADER::lenWORD, STOREHEADER::maxpower, STOREHEADER::sFun, STOREHEADER::sInd, STOREHEADER::sSym, STOREHEADER::sVec, and STOREHEADER::wildoffset.

Referenced by SetFileIndex().

4.19.6.657 DoRecovery()

```
int DoRecovery (
            int * moduletype )  [extern]
```

Reads from the recovery file and restores all necessary variables and states in FORM, so that the execution can recommence in preprocessor() as if no restart of FORM had occurred.

The recovery file is read into memory as a whole. The pointer p then points into this memory at the next non-processed data. The macros by which variables are restored, like R_SET, automatically increase p appropriately.

If something goes wrong, the function returns with a non-zero value.

Allocated memory that would be lost when overwriting the global structs with data from the file is freed first. A major part of the code deals with the restoration of pointers. The idiom we use is to memorize the original pointer value (org), allocate new memory and copy the data from the file into this memory, calculate the offset between the old pointer value and the new allocated memory position (ofs), and then correct all affected pointers (+=ofs).

We rely on the fact that several variables (especially in AM) are already assigned the correct values by the startup functions. That means, in principle, that a change in the setup files between snapshot creation and recovery will be noticed.

            WORD startebuf,
            WORD par )  [extern]
```

Converts a generic term to polynomial notation in which there are only symbols and brackets. During conversion there will be only symbols. Brackets are stripped. Objects that need 'translation' are put inside a special compiler buffer and represented by a symbol. The numbering of the extra symbols is down from the maximum. In principle there can be a problem when running into the already assigned ones. This uses the FindTree for searching in the global tree and then looks further in the AT.ebufnum. This allows fully parallel processing. Hence we need no locks. Cannot be used in the same module as ConvertToPoly.

Definition at line 510 of file notation.c.

```
void GCDclean (
            PHEAD WORD * num,
            WORD * den )  [extern]
```

Definition at line 2644 of file ratio.c.

4.19.6.711 TakeSymbolContent()

```
WORD * TakeSymbolContent (
            PHEAD WORD * in,
            WORD * term )  [extern]
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. We allow only symbols as this code is used for the polyratfun only. We have a special routine, because the generic TakeContent does too much work and speed is at a premium here. Input: in is the input expression as a sequence of terms. Output: term: the content return value: the contentfree expression. it is in new allocation, made by TermMalloc. (should be in a TermMalloc space?)

Definition at line 2434 of file ratio.c.

References GetModInverses().

```

Definition at line 1312 of file ratio.c.

4.19.6.716 TakeContent()

```
WORD * TakeContent (
            PHEAD WORD * in,
            WORD * term )  [extern]
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. Here the input is a sequence of terms in 'in' and the answer is a content-free sequence of terms. This sequence has been allocated by the Malloc1 routine in a call to EndSort, unless the expression was already content-free. In that case the input pointer is returned. The content is returned in term. This is supposed to be a separate allocation, made by TermMalloc in the calling routine.

4.21 diagrams.c File Reference

`#include "form3.h"`

Include dependency graph for diagrams.c:

Functions

- int CoCanonicalize (UBYTE ∗s)
- int DoCanonicalize (PHEAD WORD ∗term, WORD ∗params)
- WORD GenTopologies (PHEAD WORD ∗term, WORD level)
- WORD GenDiagrams (PHEAD WORD ∗term, WORD level)
- int DoTopologyCanonicalize (PHEAD WORD ∗term, WORD vert, WORD edge, WORD ∗args)
- int DoShattering (PHEAD WORD ∗connect, WORD ∗environ, WORD ∗partitions, WORD nvert)

4.21.1 Detailed Description

Contains the wrapper routines for diagram manipulations.

Definition in file diagrams.c.

4.21.2 Function Documentation

4.21.2.1 CoCanonicalize()

```
int CoCanonicalize (
            UBYTE * s )
```

Definition at line 64 of file diagrams.c.

4.21.2.2 DoCanonicalize()

```
int DoCanonicalize (
            PHEAD WORD * term,
            WORD * params )
```

Definition at line 185 of file diagrams.c.

4.21.2.3 GenTopologies()

```
WORD GenTopologies (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 348 of file diagrams.c.

4.21.2.4 GenDiagrams()

```
WORD GenDiagrams (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 401 of file diagrams.c.

4.21.2.5 DoTopologyCanonicalize()

```
int DoTopologyCanonicalize (
            PHEAD WORD * term,
            WORD vert,
            WORD edge,
            WORD * args )
```

Definition at line 428 of file diagrams.c.

4.21.2.6 DoShattering()

```
int DoShattering (
            PHEAD WORD * connect,
            WORD * environ,
            WORD * partitions,
            WORD nvert )
```

Definition at line 639 of file diagrams.c.

/* #] License : */
/*
    #[ Includes : diagrams.c
*/

#include "form3.h"

static WORD one = 1;

/*
    #] Includes :
    #[ CoCanonicalize :

    Syntax:
        Canonicalize,mainoption,...
    With the main options currently:
        Canonicalize,topology,vertexfunction,edgefunction,OutDollar,extraoptions;
        Canonicalize,polynomial,InDollar,set_or_setname_or_dollar,OutDollar,extraoptions;
    The vertex function needs to have the format (assume it is called vx):
        vx(p1,p2,-p3)  or vx(-p1,p2,p3,-p4) etc.
    The external lines have a vertex with only one line.
    All momenta that form connections should be unique.
    In principle the - signs are not relevant for the topology, but they
    may exist already in the remaining part of the diagram. They are also
    part of the canonical form.
    The edge function can be used in different ways, depending on the options.
    The extraoption(s) should be nonnegative integers or $variables that evaluate
    into nonnegative integers (integers less than 2^31).
    The Indollar variable contains the polynomial to be canonicalized.
    The OutDollar variable should be the name of a $-variable (as in $out) which
    will be filled with a replace_ function. The canonicalization can then
    be executed in the whole term with the   Multiply $out;  command.
*/

4.23.1 Detailed Description

Contains the code pertaining to dictionaries Commands are: #opendictionary name #closedictionary #selectdictionary name <options> There can be several dictionaries, but only one can be active. Defining elements is done with #add object: "replacement" Replacements are strings when a dictionary is for output translation. Objects can be 1: a number (rational) 2: a variable 3: ∗ ^ 4: a function with arguments

4.23.2 Function Documentation

4.23.2.1 TransformRational()

```
VOID TransformRational (
            UWORD * a,
            WORD na )
```

Definition at line 71 of file dict.c.

4.23.2.2 IsMultiplySign()

```
int IsMultiplySign (
            VOID  )
```

Definition at line 218 of file dict.c.

4.23.2.3 IsExponentSign()

```
int IsExponentSign (
            VOID  )
```

Definition at line 237 of file dict.c.

4.23.2.4 FindSymbol()

```
UBYTE * FindSymbol (
            WORD num )
```

Definition at line 256 of file dict.c.

4.23.2.5 FindVector()

```
UBYTE * FindVector (
            WORD num )
```

Definition at line 277 of file dict.c.

4.23.2.6 FindIndex()

```
UBYTE * FindIndex (
            WORD num )
```

Definition at line 299 of file dict.c.

4.23.2.7 FindFunction()

```
UBYTE * FindFunction (
            WORD num )
```

Definition at line 321 of file dict.c.

4.23.2.8 FindFunWithArgs()

```
UBYTE * FindFunWithArgs (
            WORD * t )
```

Definition at line 343 of file dict.c.

4.23.2.9 FindExtraSymbol()

```
UBYTE * FindExtraSymbol (
            WORD num )
```

Definition at line 375 of file dict.c.

4.23.2.10 FindDictionary()

```
int FindDictionary (
            UBYTE * name )
```

Definition at line 432 of file dict.c.

4.23.2.11 AddDictionary()

```
int AddDictionary (
            UBYTE * name )
```

Definition at line 447 of file dict.c.

4.23.2.12 AddToDictionary()

```
int AddToDictionary (
            DICTIONARY * dict,
            UBYTE * left,
            UBYTE * right )
```

Definition at line 489 of file dict.c.

4.23.2.13 UseDictionary()

```
int UseDictionary (
            UBYTE * name,
            UBYTE * options )
```

Definition at line 764 of file dict.c.

4.23.2.14 SetDictionaryOptions()

```
int SetDictionaryOptions (
            UBYTE * options )
```

Definition at line 788 of file dict.c.

4.23.2.15 UnSetDictionary()

```
void UnSetDictionary (
            VOID  )
```

Definition at line 881 of file dict.c.

4.23.2.16 RemoveDictionary()

```
void RemoveDictionary (
            DICTIONARY * dict )
```

Definition at line 900 of file dict.c.

4.23.2.17 ShrinkDictionary()

```
void ShrinkDictionary (
            DICTIONARY * dict )
```

Definition at line 943 of file dict.c.

4.23.2.18 DoPreOpenDictionary()

```
int DoPreOpenDictionary (
            UBYTE * s )
```

Definition at line 957 of file dict.c.

4.23.2.19 DoPreCloseDictionary()

```
int DoPreCloseDictionary (
            UBYTE * s )
```

Definition at line 996 of file dict.c.

4.23.2.20 DoPreUseDictionary()

```
int DoPreUseDictionary (
            UBYTE * s )
```

Definition at line 1020 of file dict.c.

4.23.2.21 DoPreAdd()

```
int DoPreAdd (
            UBYTE * s )
```

Definition at line 1065 of file dict.c.

4.23.2.22 DictToBytes()

```
LONG DictToBytes (
            DICTIONARY * dict,
            UBYTE * buf )
```

Definition at line 1117 of file dict.c.

4.23.2.23 DictFromBytes()

```
DICTIONARY * DictFromBytes (
            UBYTE * buf )
```

Definition at line 1150 of file dict.c.

4.24 dict.c

4.25.1 Detailed Description

The routines that deal with the dollar variables. The name administration is to be found in the file names.c

Definition in file dollar.c.

4.25.2 Macro Definition Documentation

4.25.2.1 STEP2

```
#define STEP2
```

Factors a dollar expression. Notation: d->nfactors becomes nonzero. if the number of factors is one, we leave d->factors zero. Otherwise factors is an array of pointers to the factors. These are pointers of the type FACDOLLAR. fd->where pointer to contents in term notation fd->size size of the buffer fd->where points to fd->type DOLNUMBER or DOLTERMS fd->value value if type is DOLNUMBER and it fits in a WORD.

Definition at line 2948 of file dollar.c.

4.25.3 Function Documentation

4.25.3.1 CatchDollar()

```
int CatchDollar (
            int par )
```

Definition at line 54 of file dollar.c.

4.25.3.2 AssignDollar()

```
int AssignDollar (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 209 of file dollar.c.

4.25.3.3 WriteDollarToBuffer()

```
UBYTE * WriteDollarToBuffer (
            WORD numdollar,
            WORD par )
```

Definition at line 596 of file dollar.c.

4.25.3.4 WriteDollarFactorToBuffer()

```
UBYTE * WriteDollarFactorToBuffer (
            WORD numdollar,
            WORD numfac,
            WORD par )
```

Definition at line 687 of file dollar.c.

4.25.3.5 AddToDollarBuffer()

```
void AddToDollarBuffer (
            UBYTE * s )
```

Definition at line 762 of file dollar.c.

4.25.3.6 TermAssign()

```
void TermAssign (
            WORD * term )
```

Definition at line 803 of file dollar.c.

4.25.3.7 PutTermInDollar()

```
int PutTermInDollar (
            WORD * term,
            WORD numdollar )
```

Definition at line 863 of file dollar.c.

4.25.3.8 WildDollars()

```
void WildDollars (
            PHEAD WORD * term )
```

Definition at line 893 of file dollar.c.

4.25.3.9 DolToTensor()

```
WORD DolToTensor (
            PHEAD WORD numdollar )
```

Definition at line 1086 of file dollar.c.

4.25.3.10 DolToFunction()

```
WORD DolToFunction (
            PHEAD WORD numdollar )
```

Definition at line 1147 of file dollar.c.

4.25.3.11 DolToVector()

```
WORD DolToVector (
            PHEAD WORD numdollar )
```

Definition at line 1204 of file dollar.c.

4.25.3.12 DolToNumber()

```
WORD DolToNumber (
            PHEAD WORD numdollar )
```

Definition at line 1268 of file dollar.c.

4.25.3.13 DolToSymbol()

```
WORD DolToSymbol (
            PHEAD WORD numdollar )
```

Definition at line 1327 of file dollar.c.

4.25.3.14 DolToIndex()

```
WORD DolToIndex (
            PHEAD WORD numdollar )
```

Definition at line 1381 of file dollar.c.

4.25.3.15 DolToTerms()

```
DOLLARS DolToTerms (
            PHEAD WORD numdollar )
```

Definition at line 1462 of file dollar.c.

4.25.3.16 DolToLong()

```
LONG DolToLong (
            PHEAD WORD numdollar )
```

Definition at line 1610 of file dollar.c.

4.25.3.17 ExecInside()

```
int ExecInside (
            UBYTE * s )
```

Definition at line 1685 of file dollar.c.

4.25.3.18 InsideDollar()

```
int InsideDollar (
            PHEAD WORD * ll,
            WORD level )
```

Definition at line 1750 of file dollar.c.

4.25.3.19 ExchangeDollars()

```
void ExchangeDollars (
            int num1,
            int num2 )
```

Definition at line 1844 of file dollar.c.

4.25.3.20 TermsInDollar()

```
LONG TermsInDollar (
            WORD num )
```

Definition at line 1862 of file dollar.c.

4.25.3.21 SizeOfDollar()

```
LONG SizeOfDollar (
            WORD num )
```

Definition at line 1911 of file dollar.c.

4.25.3.22 PreIfDollarEval()

```
UBYTE * PreIfDollarEval (
            UBYTE * s,
            int * value )
```

Definition at line 1973 of file dollar.c.

4.25.3.23 TranslateExpression()

```
WORD * TranslateExpression (
            UBYTE * s )
```

Definition at line 2155 of file dollar.c.

4.25.3.24 IsSetMember()

```
int IsSetMember (
            WORD * buffer,
            WORD numset )
```

Definition at line 2212 of file dollar.c.

4.25.3.25 IsMultipleOf()

```
int IsMultipleOf (
            WORD * buf1,
            WORD * buf2 )
```

Definition at line 2393 of file dollar.c.

4.25.3.26 TwoExprCompare()

```
int TwoExprCompare (
            WORD * buf1,
            WORD * buf2,
            int oprtr )
```

Definition at line 2468 of file dollar.c.

4.25.3.27 DollarRaiseLow()

```
int DollarRaiseLow (
            UBYTE * name,
            LONG value )
```

Definition at line 2547 of file dollar.c.

4.25.3.28 EvalDoLoopArg()

```
WORD EvalDoLoopArg (
            PHEAD WORD * arg,
            WORD par )
```

Evaluates one argument of a do loop. Such an argument is constructed from SNUMBERs DOLLAREXPRESSIONs and possibly DOLLAREXPR2s which indicate factors of the preceeding dollar. Hence we have SNUMBER,num DOLLAREXPRESSION,numdollar DOLLAREXPRESSION,numdollar,DOLLAREXPR2,numfactor DOLLAREXPRESSION,numdollar,DOLLAREXPR2,numfactor,DOLLAREXPR2,numfactor etc. Because we have a do-loop at every stage we should have a number. The notation in DOLLAREXPR2 is that $>=$ 0 is number of yet another dollar and $<$ 0 is -n-1 with n the array element or zero. The return value is the (short) number. The routine works its way through the list in a recursive manner.

Definition at line 2646 of file dollar.c.

References EvalDoLoopArg().

Referenced by EvalDoLoopArg().

Here is the call graph for this function:

4.25.3.29 TestDoLoop()

```
WORD TestDoLoop (
            PHEAD WORD * lhsbuf,
            WORD level )
```

Definition at line 2757 of file dollar.c.

4.25.3.30 TestEndDoLoop()

```
WORD TestEndDoLoop (
            PHEAD WORD * lhsbuf,
            WORD level )
```

Definition at line 2835 of file dollar.c.

4.25.3.31 DollarFactorize()

```
int DollarFactorize (
            PHEAD WORD numdollar )
```

Definition at line 2950 of file dollar.c.

4.25.3.32 CleanDollarFactors()

```
void CleanDollarFactors (
            DOLLARS d )
```

Definition at line 3549 of file dollar.c.

4.25.3.33 TakeDollarContent()

```
WORD * TakeDollarContent (
            PHEAD WORD * dollarbuffer,
            WORD ** factor )
```

Definition at line 3570 of file dollar.c.

4.25.3.34 MakeDollarInteger()

```
WORD * MakeDollarInteger (
            PHEAD WORD * bufin,
            WORD ** bufout )
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in bufin. The number that comes out is the return value. The normalized argument is in bufout.

Definition at line 3622 of file dollar.c.

References EndSort(), Generator(), and NewSort().

Here is the call graph for this function:

4.25.3.35 MakeDollarMod()

```
WORD * MakeDollarMod (
            PHEAD WORD * buffer,
            WORD ** bufout )
```

Similar to MakeDollarInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3796 of file dollar.c.

References EndSort(), Generator(), GetModInverses(), and NewSort().

Here is the call graph for this function:

4.25.3.36 GetDolNum()

```
int GetDolNum (
            PHEAD WORD * t,
            WORD * tstop )
```

Definition at line 3841 of file dollar.c.

4.25.3.37 AddPotModdollar()

```
void AddPotModdollar (
            WORD numdollar )
```

Adds a $-variable specified by *numdollar* to the list of potentially modified $-variables unless it has already been included in the list.

Parameters

numdollar	The index of the $-variable to be added.

Definition at line 3954 of file dollar.c.

    #] CatchDollar :
    #[ AssignDollar :

    To be called from Generator. Assigns an expression to a $ variable.
    This one is slightly different from CatchDollar.
    We have no easy buffer this time.
    We will have to hack our way using what we normally use for functions.

    Note that in the threaded case we trust the user. That means that
    we are not going to recheck whether there is a maximum, minimum or sum.
    If the user says it is like that, we treat it like that.
    We only check that in this centralized version MODLOCAL isn't used.

    In a later stage dtype could be used for actually checking MODMAX
    and MODMIN cases.

4.27.1 Detailed Description

The routines that start the execution phase of a module. It also contains the routines for placing the bracket subterm.

Definition in file execute.c.

4.27.2 Macro Definition Documentation

4.27.2.1 CURRENTBRACKET

```
#define CURRENTBRACKET 1
```

Definition at line 2484 of file execute.c.

4.27.2.2 BRACKETCURRENTEXPR

```
#define BRACKETCURRENTEXPR 2
```

Definition at line 2485 of file execute.c.

4.27.2.3 BRACKETOTHEREXPR

```
#define BRACKETOTHEREXPR 3
```

Definition at line 2486 of file execute.c.

4.27.2.4 NOBRACKETACTIVE

```
#define NOBRACKETACTIVE 4
```

Definition at line 2487 of file execute.c.

4.27.3 Function Documentation

4.27.3.1 CleanExpr()

```
WORD CleanExpr (
            WORD par )
```

Definition at line 47 of file execute.c.

4.27.3.2 PopVariables()

```
WORD PopVariables ( )
```

Definition at line 210 of file execute.c.

4.27.3.3 MakeGlobal()

```
VOID MakeGlobal ( )
```

Definition at line 377 of file execute.c.

4.27.3.4 TestDrop()

```
VOID TestDrop ( )
```

Definition at line 474 of file execute.c.

4.27.3.5 PutInVflags()

```
void PutInVflags (
            WORD nexpr )
```

Definition at line 552 of file execute.c.

4.27.3.6 DoExecute()

```
WORD DoExecute (
            WORD par,
            WORD skip )
```

Definition at line 600 of file execute.c.

4.27.3.7 PutBracket()

```
WORD PutBracket (
            PHEAD WORD * termin )
```

Definition at line 1063 of file execute.c.

4.27.3.8 SpecialCleanup()

```
VOID SpecialCleanup (
            PHEAD0  )
```

Definition at line 1572 of file execute.c.

4.27.3.9 SetMods()

```
void SetMods ( )
```

Definition at line 1586 of file execute.c.

4.27.3.10 UnSetMods()

```
void UnSetMods ( )
```

Definition at line 1604 of file execute.c.

4.27.3.11 ExchangeExpressions()

```
void ExchangeExpressions (
            int num1,
            int num2 )
```

Definition at line 1619 of file execute.c.

4.27.3.12 GetFirstBracket()

```
int GetFirstBracket (
            WORD * term,
            int num )
```

Definition at line 1693 of file execute.c.

4.27.3.13 GetFirstTerm()

```
int GetFirstTerm (
            WORD * term,
            int num )
```

Definition at line 1803 of file execute.c.

4.27.3.14 GetContent()

```
int GetContent (
            WORD * content,
            int num )
```

Definition at line 1898 of file execute.c.

4.27.3.15 CleanupTerm()

```
int CleanupTerm (
            WORD * term )
```

Definition at line 2015 of file execute.c.

4.27.3.16 ContentMerge()

```
WORD ContentMerge (
            PHEAD WORD * content,
            WORD * term )
```

Definition at line 2039 of file execute.c.

4.27.3.17 TermsInExpression()

```
LONG TermsInExpression (
            WORD num )
```

Definition at line 2303 of file execute.c.

4.27.3.18 SizeOfExpression()

```
LONG SizeOfExpression (
            WORD num )
```

Definition at line 2315 of file execute.c.

4.27.3.19 UpdatePositions()

```
void UpdatePositions ( )
```

Definition at line 2327 of file execute.c.

4.27.3.20 CountTerms1()

```
LONG CountTerms1 (
            PHEAD0  )
```

Definition at line 2381 of file execute.c.

4.27.3.21 TermsInBracket()

```
LONG TermsInBracket (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 2489 of file execute.c.

/*
        #] DoExecute :
        #[ PutBracket :

    Routine uses the bracket info to split a term into two pieces:
    1: the part outside the bracket, and
    2: the part inside the bracket.
    These parts are separated by a subterm of type HAAKJE.
    This subterm looks like: HAAKJE,3,level
    The level is used for nestings of brackets. The print routines
    cannot handle this yet (31-Mar-1988).

    The Bracket selector is in AT.BrackBuf in the form of a regular term,
    but without coefficient.
    When AR.BracketOn < 0 we have a socalled antibracket. The main effect
    is an exchange of the inner and outer part and where the coefficient goes.

    Routine recoded to facilitate b p1,p2; etc for dotproducts and tensors
    15-oct-1991

4.29.1 Detailed Description

The system that takes care of communication with external programs.

Definition in file extcmd.c.

4.29.2 Function Documentation

4.29.2.1 openExternalChannel()

```
int openExternalChannel (
            UBYTE * cmd,
            int daemonize,
            UBYTE * shellname,
            UBYTE * stderrname )
```

Definition at line 236 of file extcmd.c.

4.29.2.2 initPresetExternalChannels()

```
int initPresetExternalChannels (
            UBYTE * theline,
            int thetimeout )
```

Definition at line 238 of file extcmd.c.

4.29.2.3 closeExternalChannel()

```
int closeExternalChannel (
            int n )
```

Definition at line 239 of file extcmd.c.

4.29.2.4 selectExternalChannel()

```
int selectExternalChannel (
            int n )
```

Definition at line 240 of file extcmd.c.

4.29.2.5 getCurrentExternalChannel()

```
int getCurrentExternalChannel ( )
```

Definition at line 241 of file extcmd.c.

4.29.2.6 closeAllExternalChannels()

```
void closeAllExternalChannels ( )
```

Definition at line 242 of file extcmd.c.

00032     #[ Documentation :
00033
00034     This module is written by M.Tentyukov as a part of implementation of
00035     interaction between FORM and external processes, first release
```

```
    09.04.2004. A part of this code is copyied from the DIANA project
    written by M. Tentyukov and published under the GPL version 2 as
    published by the Free Software Foundation.  The code of this module
    is NOT covered by GPL; it can be used under the terms of the FORM
    License http://www.nikhef.nl/~form/license.html

    This file is completely re-written by M.Tentyukov in May 2006.
    Since the interface was changed, the public function were changed,
    also. A new publc functions were added: initPresetExternalChannels()
    (see comments just before this function in the present file) and
    setKillModeForExternalChannel (a pointer, not a function).

    If a macro WITHEXTERNALCHANNEL is not defined, all public punctions
    are stubs returning failure.

    The idea is to start an external command  swallowing
    its stdin and stdout. This can be done by means of the function
    int openExternalChannel(cmd,daemonize,shellname,stderrname), where
    cmd is a command to run,
    daemonize: if !=0 then start the command in the "daemon" mode,
    shellname: if !=NULL, execute the command in a subshell,
    stderrname: if != NULL, redirect stderr of the command to this file.
    The function returns some small positive integer number (the
    descriptor of a newly created external channel), or -1 on failure.

    After the command is started, it becomes a _current_ opened external
    channel. The buffer can be sent to its stdin by a function
    int writeBufToExtChannel(buf, n)
    (here buf is a pointer to the buffer, n is the length in bytes; the
    function returns 0 in success, or -1 on failure),
    or one character can be read from its stdout by
    means of the function
    int getcFromExtChannel().

    The latter returns the
    character casted to integer, or something <0. This can be -2 (if there
    is no current external channel) or EOF, if the external program closes
    its stdout, or if the external program outputs a string coinciding
    with a _terminator_.

    By default, the terminator if an empty line. For the current external
    channel it can be set by means of the function
    int setTerminatorForExternalChannel(newterminaror).
    The function returns 0 in success, or !0 if something is wrong (no
    current channel, too long terminator).

    After getcFromExtChannel() returns EOF, the current channel becomes
    undefined. Any further attempts to read information by
    getcFromExtChannel() result in -2. To set (re-set) a current channel,
    the function
    int selectExternalChannel(n)
    can be used. This function accepts the valid external channel
    descriptor (returned by openExternalChannel) and returns the
    descriptor of a previous current channel (0, if there was no current
    channel, or -1, if the external channel descriptor is invalid).
    If n == 0, the function undefine the current external channel.

    The function
    int closeExternalChannel(n)
    destroys the opened external channel with the descriptor n. It returns
    0 in success, or -1 on failure. If the corresponding external channel
    was the current one, the current channel becomes undefined. If n==0,
    the function closes the current external channel.

    The function
    int getCurrentExternalChannel(void)
    returns the descriptor if the current external channel, or 0 , if
    there is no current external channel.

    The function
    void closeAllExternalChannels(void)

    destroys all opened external channels.

    List of all public functions:
    int openExternalChannel(UBYTE *cmd,int daemonize,UBYTE *shellname, UBYTE * stderrname);
    int initPresetExternalChannels(UBYTE *theline, int thetimeout);
    int setTerminatorForExternalChannel(char *newterminaror);
    int setKillModeForExternalChannel(int signum, int sentToWholeGroup);
    int closeExternalChannel(int n);
    int selectExternalChannel(int n);
    int writeBufToExtChannel(char *buf,int n);
    int getcFromExtChannel(void);
    int getCurrentExternalChannel(void);
    void closeAllExternalChannels(void);

    ATTENTION!
```

```

    Four of them:
    1 setTerminatorForExternalChannel
    2 setKillModeForExternalChannel
    3 writeBufToExtChannel
    4 getcFromExtChannel

    are NOT functions, but variables (pointers) of a corrsponding type.
    They are initialised by proper values to avoid repeated error checking.

    All public functions are independent of realization hidden in this module.
    All other functions may have a returned type/parameters type local w.r.t.
    this module; they are not declared outside of this file.

/*
    #] FactorIn :
    #[ FactorInExpr :

    This routine tests for a factor in an active or hidden expression.

    The factor from the last call is stored in a cache.
    Main problem here is whether the cache is global or private to each thread.
    A global cache gives most likely the same traffic jam for the computation
    as a local cache. The local cache may stay valid longer.
    In the future we may make it such that threads can look at the cache
    of the others, or even whether a certain factor is under construction.

4.33.1 Detailed Description

Pattern matching of symbols and dotproducts. There are various routines because of the options in the id-statements like once, only, multi and many. These are amoung the oldest routines in FORM and that can be noticed, because the interplay with the function matching is not complete. When we match functions and halfway we fail we can backtrack properly. With the symbols, the dotproducts and the vectors (in pattern.c) there is no proper backtracking. Hence the routines here need still quite some work or may even have to be rewritten.

4.33.2 Function Documentation

4.33.2.1 FindOnly()

```
WORD FindOnly (
            PHEAD WORD * term,
            WORD * pattern )
```

Definition at line 61 of file findpat.c.

4.33.2.2 FindOnce()

```
WORD FindOnce (
            PHEAD WORD * term,
            WORD * pattern )
```

Definition at line 419 of file findpat.c.

4.33.2.3 FindMulti()

```
WORD FindMulti (
            PHEAD WORD * term,
            WORD * pattern )
```

Definition at line 954 of file findpat.c.

4.33.2.4 FindRest()

```
WORD FindRest (
            PHEAD WORD * term,
            WORD * pattern )
```

Definition at line 1070 of file findpat.c.

4.35.1 Detailed Description

Contains critical defines for the compilation process Also contains the inclusion of all necessary header files. There are also some system dependencies concerning file functions.

Definition in file form3.h.

4.35.2 Macro Definition Documentation

4.35.2.1 MAJORVERSION

```
#define MAJORVERSION 4
```

Definition at line 47 of file form3.h.

4.35.2.2 MINORVERSION

```
#define MINORVERSION 2
```

Definition at line 48 of file form3.h.

4.35.2.3 PRODUCTIONDATE

```
#define PRODUCTIONDATE "06-jul-2017"
```

Definition at line 53 of file form3.h.

4.35.2.4 inline

```
#define inline
```

Definition at line 131 of file form3.h.

4.35.2.5 NDEBUG

```
#define NDEBUG
```

Definition at line 167 of file form3.h.

4.35.2.6 STATIC_ASSERT

```
#define STATIC_ASSERT(
            condition ) STATIC_ASSERT__1(condition,__LINE__)
```

Definition at line 175 of file form3.h.

4.35.2.7 STATIC_ASSERT__1

```
#define STATIC_ASSERT__1(
            X,
            L ) STATIC_ASSERT__2(X,L)
```

Definition at line 176 of file form3.h.

4.35.2.8 STATIC_ASSERT__2

```
#define STATIC_ASSERT__2(
            X,
            L ) STATIC_ASSERT__3(X,L)
```

Definition at line 177 of file form3.h.

4.35.2.9 STATIC_ASSERT__3

```
#define STATIC_ASSERT__3(
            X,
            L )  typedef char static_assertion_failed_##L[(!!(X))*2-1]
```

Definition at line 178 of file form3.h.

4.35.2.10 TOPBITONLY

```
#define TOPBITONLY ((ULONG)1 << (BITSINWORD - 1)) /* 0x00008000UL */
```

Definition at line 308 of file form3.h.

4.35.2.11 TOPLONGBITONLY

```
#define TOPLONGBITONLY ((ULONG)1 << (BITSINLONG - 1)) /* 0x80000000UL */
```

Definition at line 309 of file form3.h.

4.35.2.12 SPECMASK

```
#define SPECMASK ((UWORD)1 << (BITSINWORD - 1)) /* 0x8000U */
```

Definition at line 310 of file form3.h.

4.35.2.13 WILDMASK

```
#define WILDMASK ((UWORD)1 << (BITSINWORD - 2)) /* 0x4000U */
```

Definition at line 311 of file form3.h.

4.35.2.14 WORDMASK

```
#define WORDMASK ((ULONG)FULLMAX - 1) /* 0x0000FFFFUL */
```

Definition at line 312 of file form3.h.

4.35.2.15 AWORDMASK

```
#define AWORDMASK (WORDMASK << BITSINWORD) /* 0xFFFF0000UL */
```

Definition at line 313 of file form3.h.

4.35.2.16 FULLMAX

```
#define FULLMAX ((LONG)1 << BITSINWORD) /* 0x00010000L */
```

Definition at line 314 of file form3.h.

4.35.2.17 MAXPOSITIVE

```
#define MAXPOSITIVE ((LONG)(TOPBITONLY - 1)) /* 0x00007FFFL */
```

Definition at line 315 of file form3.h.

4.35.2.18 MAXLONG

```
#define MAXLONG ((LONG)(TOPLONGBITONLY - 1)) /* 0x7FFFFFFFL */
```

Definition at line 316 of file form3.h.

4.35.2.19 MAXPOSITIVE2

```
#define MAXPOSITIVE2 (MAXPOSITIVE / 2) /* 0x00003FFFL */
```

Definition at line 317 of file form3.h.

4.35.2.20 MAXPOSITIVE4

```
#define MAXPOSITIVE4 (MAXPOSITIVE / 4) /* 0x00001FFFL */
```

Definition at line 318 of file form3.h.

4.35.2.21 alignof

```
#define alignof(
              type ) offsetof(struct { char c_; type x_; }, x_)
```

Definition at line 334 of file form3.h.

4.35.2.22 PADDUMMY

```
#define PADDUMMY(
              type,
              size )  UBYTE d_u_m_m_y[alignof(type) - ((size) & (alignof(type) - 1))]
```

Definition at line 379 of file form3.h.

4.35.2.23 PADPOSITION

```
#define PADPOSITION(
              ptr_,
              long_,
              int_,
              word_,
              byte_ )
```

Value:

```
PADDUMMY(off_t, \
    + sizeof(int *) * (ptr_) \
    + sizeof(LONG)  * (long_) \
    + sizeof(int)   * (int_) \
    + sizeof(WORD)  * (word_) \
    + sizeof(UBYTE) * (byte_) \
)
```

Definition at line 381 of file form3.h.

4.35.2.24 PADPOINTER

```
#define PADPOINTER(
                long_,
                int_,
                word_,
                byte_ )
```

Value:

```

    + sizeof(LONG)  * (long_) \
    + sizeof(int)   * (int_) \
    + sizeof(WORD)  * (word_) \
    + sizeof(UBYTE) * (byte_) \
)
```

Definition at line 389 of file form3.h.

4.35.2.25 PADLONG

```
#define PADLONG(
                int_,
                word_,
                byte_ )
```

Value:

```
PADDUMMY(LONG, \
    + sizeof(int)   * (int_) \
    + sizeof(WORD)  * (word_) \
    + sizeof(UBYTE) * (byte_) \
)
```

Definition at line 396 of file form3.h.

4.35.2.26 PADINT

```
#define PADINT(
                word_,
                byte_ )
```

Value:

```
PADDUMMY(int, \
    + sizeof(WORD)  * (word_) \
    + sizeof(UBYTE) * (byte_) \
)
```

Definition at line 402 of file form3.h.

4.35.2.27 PADWORD

```
#define PADWORD(
                byte_ )
```

Value:

```
PADDUMMY(WORD, \
    + sizeof(UBYTE) * (byte_) \
)
```

Definition at line 407 of file form3.h.

4.35.2.28 WITHSORTBOTS

```
#define WITHSORTBOTS
```

Definition at line 417 of file form3.h.

4.35.2.29 FILES

```
#define FILES FILE
```

Definition at line 495 of file form3.h.

4.35.2.30 Uopen

```
#define Uopen(
            x,
            y ) fopen(x,y)
```

Definition at line 496 of file form3.h.

4.35.2.31 Uflush

```
#define Uflush(
            x ) fflush(x)
```

Definition at line 497 of file form3.h.

4.35.2.32 Uclose

```
#define Uclose(
            x ) fclose(x)
```

Definition at line 498 of file form3.h.

4.35.2.33 Uread

```
#define Uread(
            x,
            y,
            z,
            u ) fread(x,y,z,u)
```

Definition at line 499 of file form3.h.

4.35.2.34 Uwrite

```
#define Uwrite(
            x,
            y,
            z,
            u ) fwrite(x,y,z,u)
```

Definition at line 500 of file form3.h.

4.35.2.35 Usetbuf

```
#define Usetbuf(
            x,
            y ) setbuf(x,y)
```

Definition at line 501 of file form3.h.

4.35.2.36 Useek

```
#define Useek(
            x,
            y,
            z ) fseek(x,y,z)
```

Definition at line 502 of file form3.h.

4.35.2.37 Utell

```
#define Utell(
            x ) ftell(x)
```

Definition at line 503 of file form3.h.

4.35.2.38 Ugetpos

```
#define Ugetpos(
            x,
            y ) fgetpos(x,y)
```

Definition at line 504 of file form3.h.

4.35.2.39 Usetpos

```
#define Usetpos(
            x,
            y ) fsetpos(x,y)
```

Definition at line 505 of file form3.h.

4.35.2.40 Usync

```
#define Usync(
              x ) fflush(x)
```

Definition at line 506 of file form3.h.

4.35.2.41 Utruncate

```
#define Utruncate(
              x ) _chsize(_fileno(x),0)
```

Definition at line 507 of file form3.h.

4.35.2.42 Ustdout

```
#define Ustdout stdout
```

Definition at line 508 of file form3.h.

4.35.2.43 MAX_OPEN_FILES

```
#define MAX_OPEN_FILES FOPEN_MAX
```

Definition at line 509 of file form3.h.

4.35.2.44 bzero

```
#define bzero(
              b,
              len ) (memset((b), 0, (len)), (void)0)
```

Definition at line 510 of file form3.h.

4.35.2.45 GetPID

```
#define GetPID( ) ((LONG)GetCurrentProcessId())
```

Definition at line 511 of file form3.h.

4.35.3 Typedef Documentation

/*
 * Macros inserted to the end of a structure to align the whole structure.
 *
 * In the currently available systems,
 *   sizeof(POSITION) >= sizeof(pointers) == sizeof(LONG) >= sizeof(int)
 *                    >= sizeof(WORD) >= sizeof(UBYTE) = 1.
 * (POSITION is defined in struct.h and contains only an off_t variable.)
 * Thus, if we put members of a structure in this order and use those macros,
 * then we can align the data without relying on extra paddings added by
 * the compiler. For example,
 *   typedef struct {
 *     int *a;
 *     LONG b;
 *     WORD c[2];
 *     UBYTE d;
 *     PADPOINTER(1,0,2,1);
 *   } A;
 *   typedef struct {
 *     POSITION p;
 *     A a;  // aligned same as pointers
 *     int *b;
 *     LONG c;
 *     UBYTE d;
 *     PADPOSITION(1,1,0,0,1+sizeof(A));
 *   } B;
 * The cost for the use of those PADXXX functions is a padding (>= 1 byte) will
 * be always inserted even in the case that no padding is actually needed.
 *
 * Note that there is a 32-bit system in which off_t is aligned on 8-byte
```

```
 * boundary, (e.g., Cygwin).

4.37.1 Detailed Description

The definition the default values for certain buffer sizes etc.

Definition in file fsizes.h.

4.37.2 Macro Definition Documentation

4.37.2.1 MAXPRENAMESIZE

```
#define MAXPRENAMESIZE 128
```

Definition at line 36 of file fsizes.h.

4.37.2.2 MAXPOWER

```
#define MAXPOWER 10000
```

Definition at line 58 of file fsizes.h.

4.37.2.3 MAXVARIABLES

```
#define MAXVARIABLES 8050
```

Definition at line 59 of file fsizes.h.

4.37.2.4 MAXDOLLARVARIABLES

```
#define MAXDOLLARVARIABLES 32000
```

Definition at line 60 of file fsizes.h.

4.37.2.5 WILDOFFSET

```
#define WILDOFFSET 6100
```

Definition at line 61 of file fsizes.h.

4.37.2.6 MAXINNAMETREE

```
#define MAXINNAMETREE 32768
```

Definition at line 62 of file fsizes.h.

4.37.2.7 MAXDUMMIES

```
#define MAXDUMMIES 1000
```

Definition at line 63 of file fsizes.h.

4.37.2.8 WORKBUFFER

```
#define WORKBUFFER 10000000
```

Definition at line 64 of file fsizes.h.

4.37.2.9 MAXTER

```
#define MAXTER 10000
```

Definition at line 65 of file fsizes.h.

4.37.2.10 HALFMAX

```
#define HALFMAX 0x100
```

Definition at line 66 of file fsizes.h.

4.37.2.11 MAXSUBEXPRESSIONS

```
#define MAXSUBEXPRESSIONS 0x3FFF
```

Definition at line 67 of file fsizes.h.

4.37.2.12 MAXFILESTREAMSIZE

```
#define MAXFILESTREAMSIZE 1048576
```

Definition at line 68 of file fsizes.h.

4.37.2.13 MAXENAME

```
#define MAXENAME 16
```

Definition at line 70 of file fsizes.h.

4.37.2.14 MAXSAVEFUNCTION

```
#define MAXSAVEFUNCTION 16384
```

Definition at line 71 of file fsizes.h.

4.37.2.15 MAXPARLEVEL

```
#define MAXPARLEVEL 100
```

Definition at line 73 of file fsizes.h.

4.37.2.16 MAXNUMBERSIZE

```
#define MAXNUMBERSIZE 200
```

Definition at line 74 of file fsizes.h.

4.37.2.17 MAXREPEAT

```
#define MAXREPEAT 100
```

Definition at line 76 of file fsizes.h.

4.37.2.18 NORMSIZE

```
#define NORMSIZE 1000
```

Definition at line 77 of file fsizes.h.

4.37.2.19 INITNODESIZE

```
#define INITNODESIZE 10
```

Definition at line 79 of file fsizes.h.

4.37.2.20 INITNAMESIZE

```
#define INITNAMESIZE 100
```

Definition at line 80 of file fsizes.h.

4.37.2.21 NUMFIXED

```
#define NUMFIXED 128
```

Definition at line 82 of file fsizes.h.

4.37.2.22 MAXNEST

```
#define MAXNEST 100
```

Definition at line 83 of file fsizes.h.

4.37.2.23 MAXMATCH

```
#define MAXMATCH 30
```

Definition at line 84 of file fsizes.h.

4.37.2.24 MAXIF

```
#define MAXIF 20
```

Definition at line 85 of file fsizes.h.

4.37.2.25 SIZEFACS

```
#define SIZEFACS 640L
```

Definition at line 86 of file fsizes.h.

4.37.2.26 NUMFACS

```
#define NUMFACS 50

4.39.1 Detailed Description

Contains the definitions of many internal codes Rather than using numbers directly we do this by defines, making it much easier to change things. Changing things is sometimes also a good way of testing the code.

Definition in file ftypes.h.

4.39.2 Macro Definition Documentation

4.39.2.1 WITHOUTERROR

```
#define WITHOUTERROR 0
```

The next macros were introduced when TFORM was programmed. In the case of workers, each worker may need some private data. These can in principle be accessed by some posix calls but that is unnecessarily slow. The passing of a pointer to the complete data struct with private data will be much faster. And anyway, there would have to be a macro that either makes the posix call (TFORM) or doesn't (FORM). The solution by having macro's that either pass the pointer (TFORM) or don't pass it (FORM) is seen as the best solution.

In the declarations and the calling of the functions we have to use the PHEAD or the BHEAD macro, respectively, if the pointer is to be passed. These macro's contain the comma as well. Hence we need special macro's if there are no other arguments. These are called PHEAD0 and BHEAD0.
