Chapter 3

Data Structure Documentation

3.1 AllGlobals Struct Reference

`#include <structs.h>`

Collaboration diagram for AllGlobals:

Public Member Functions

- **PADPOSITION** (0, 0, 0, 0, sizeof(struct P_const)+sizeof(struct T_const)+sizeof(struct X_const))

Data Fields

- struct M_const M
- struct C_const C
- struct S_const S
- struct R_const R
- struct N_const N
- struct O_const O
- struct P_const P
- struct T_const T
- struct X_const X

3.1.1 Detailed Description

Without pthreads (FORM) the ALLGLOBALS struct has all the global variables

Definition at line 2398 of file structs.h.

3.1.2 Field Documentation

3.1.2.1 M

```
struct M_const AllGlobals::M
```

Definition at line 2399 of file structs.h.

3.1.2.2 C

```
struct C_const AllGlobals::C
```

Definition at line 2400 of file structs.h.

3.1.2.3 S

```
struct S_const AllGlobals::S
```

Definition at line 2401 of file structs.h.

3.1.2.4 R

```
struct R_const AllGlobals::R
```

Definition at line 2402 of file structs.h.

3.1.2.5 N

```
struct N_const AllGlobals::N
```

Definition at line 2403 of file structs.h.

3.1.2.6 O

```
struct O_const AllGlobals::O
```

Definition at line 2404 of file structs.h.

3.1.2.7 P

```
struct P_const AllGlobals::P
```

Definition at line 2405 of file structs.h.

3.1.2.8 T

```
struct T_const AllGlobals::T
```

Definition at line 2406 of file structs.h.

3.1.2.9 X

```
struct X_const AllGlobals::X
```

Definition at line 2407 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.2 ARGBUFFER Struct Reference

Collaboration diagram for ARGBUFFER:

Data Fields

- WORD * buffer
- DOLLARS dollar
- LONG size
- int type
- int dummy

3.2.1 Detailed Description

Definition at line 601 of file ratio.c.

3.2.2 Field Documentation

3.2.2.1 buffer

```
WORD* ARGBUFFER::buffer
```

Definition at line 602 of file ratio.c.

3.2.2.2 dollar

```
DOLLARS ARGBUFFER::dollar
```

Definition at line 603 of file ratio.c.

3.2.2.3 size

```
LONG ARGBUFFER::size
```

Definition at line 604 of file ratio.c.

3.2.2.4 type

```
int ARGBUFFER::type
```

Definition at line 605 of file ratio.c.

3.2.2.5 dummy

```
int ARGBUFFER::dummy
```

Definition at line 606 of file ratio.c.

The documentation for this struct was generated from the following file:

- ratio.c

3.3 bit_field Struct Reference

```
#include <structs.h>
```

Data Fields

- UBYTE bit_0: 1
- UBYTE bit_1: 1
- UBYTE bit_2: 1
- UBYTE bit_3: 1
- UBYTE bit_4: 1
- UBYTE bit_5: 1
- UBYTE bit_6: 1
- UBYTE bit_7: 1

3.3.1 Detailed Description

The struct bit_field is used by set_in, set_set, set_del and set_sub. They in turn are used in pre.c to toggle bits that indicate whether a character can be used as a separator of function arguments. This facility is used in the communication with external channels.

Definition at line 865 of file structs.h.

3.3.2 Field Documentation

3.3.2.1 bit_0

```
UBYTE bit_field::bit_0
```

Definition at line 866 of file structs.h.

3.3.2.2 bit_1

```
UBYTE bit_field::bit_1
```

Definition at line 867 of file structs.h.

3.3.2.3 bit_2

```
UBYTE bit_field::bit_2
```

Definition at line 868 of file structs.h.

3.3.2.4 bit_3

```
UBYTE bit_field::bit_3
```

Definition at line 869 of file structs.h.

3.3.2.5 bit_4

```
UBYTE bit_field::bit_4
```

Definition at line 870 of file structs.h.

3.3.2.6 bit_5

```
UBYTE bit_field::bit_5
```

Definition at line 871 of file structs.h.

3.3.2.7 bit_6

```
UBYTE bit_field::bit_6
```

Definition at line 872 of file structs.h.

3.3.2.8 bit_7

```
UBYTE bit_field::bit_7
```

Definition at line 873 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.4 BrAcKeTiNdEx Struct Reference

Collaboration diagram for BrAcKeTiNdEx:

Public Member Functions

- **PADPOSITION** (0, 2, 0, 0, 0)

Data Fields

- POSITION start
- POSITION next
- LONG bracket
- LONG termsinbracket

3.4.1 Detailed Description

Definition at line 304 of file structs.h.

3.4.2 Field Documentation

3.4.2.1 start

```
POSITION BrAcKeTiNdEx::start
```

Definition at line 305 of file structs.h.

3.4.2.2 next

```
POSITION BrAcKeTiNdEx::next
```

Definition at line 306 of file structs.h.

3.4.2.3 bracket

```
LONG BrAcKeTiNdEx::bracket
```

Definition at line 307 of file structs.h.

3.4.2.4 termsinbracket

```
LONG BrAcKeTiNdEx::termsinbracket
```

Definition at line 308 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.5 BrAcKeTiNfO Struct Reference

Collaboration diagram for BrAcKeTiNfO:

Data Fields

- BRACKETINDEX * indexbuffer
- WORD * bracketbuffer
- LONG bracketbuffersize
- LONG indexbuffersize
- LONG bracketfill
- LONG indexfill
- WORD SortType

3.5.1 Detailed Description

Definition at line 316 of file structs.h.

3.5.2 Field Documentation

3.5.2.1 indexbuffer

```
BRACKETINDEX* BrAcKeTiNfO::indexbuffer
```

[D]

Definition at line 317 of file structs.h.

Referenced by DoRecovery(), and FlushOut().

3.5.2.2 bracketbuffer

```
WORD* BrAcKeTiNfO::bracketbuffer
```

[D]

Definition at line 318 of file structs.h.

Referenced by DoRecovery().

3.5.2.3 bracketbuffersize

```
LONG BrAcKeTiNfO::bracketbuffersize
```

Definition at line 319 of file structs.h.

3.5.2.4 indexbuffersize

```
LONG BrAcKeTiNfO::indexbuffersize
```

Definition at line 320 of file structs.h.

3.5.2.5 bracketfill

```
LONG BrAcKeTiNfO::bracketfill
```

Definition at line 321 of file structs.h.

3.5.2.6 indexfill

```
LONG BrAcKeTiNfO::indexfill
```

Definition at line 322 of file structs.h.

3.5.2.7 SortType

```
WORD BrAcKeTiNfO::SortType
```

The sorting criterium used (like POWERFIRST etc)

Definition at line 323 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.6 bufIPstruct Struct Reference

Collaboration diagram for bufIPstruct:

Data Fields

- LONG i
- struct ExPrEsSiOn e

3.6.1 Detailed Description

Definition at line 3908 of file parallel.c.

3.6.2 Field Documentation

3.6.2.1 i

```
LONG bufIPstruct::i
```

Definition at line 3909 of file parallel.c.

3.6.2.2 e

```
struct ExPrEsSiOn bufIPstruct::e
```

Definition at line 3910 of file parallel.c.

The documentation for this struct was generated from the following file:

- parallel.c

3.7 C_const Struct Reference

```
#include <structs.h>
```

Collaboration diagram for C_const:

Public Member Functions

3.7.1 Detailed Description

The C_const struct is part of the global data and resides in the ALLGLOBALS struct A under the name #C. We see it used with the macro AC as in AC.exprnames. It contains variables that involve the compiler and objects set during compilation.

Definition at line 1565 of file structs.h.

3.7.2 Field Documentation

3.7.2.1 separators

```
set_of_char C_const::separators
```

Separators in #call and #do

Definition at line 1566 of file structs.h.

3.7.2.2 StoreFileSize

```
POSITION C_const::StoreFileSize
```

Definition at line 1567 of file structs.h.

3.7.2.3 dollarnames

```
NAMETREE* C_const::dollarnames
```

[D] Names of dollar variables

Definition at line 1568 of file structs.h.

3.7.2.4 exprnames

```
NAMETREE* C_const::exprnames
```

[D] Names of expressions

Definition at line 1569 of file structs.h.

3.7.2.5 varnames

```
NAMETREE* C_const::varnames
```

[D] Names of regular variables

Definition at line 1570 of file structs.h.

3.7.2.6 ChannelList

```
LIST C_const::ChannelList
```

Used for the #write statement. Contains CHANNEL

Definition at line 1571 of file structs.h.

3.7.2.7 DubiousList

```
LIST C_const::DubiousList
```

List of dubious variables. Contains DUBIOUSV. If not empty -> no execution

Definition at line 1573 of file structs.h.

3.7.2.8 FunctionList

```
LIST C_const::FunctionList
```

List of functions and properties. Contains FUNCTIONS

Definition at line 1575 of file structs.h.

3.7.2.9 ExpressionList

```
LIST C_const::ExpressionList
```

List of expressions, locations etc.

Definition at line 1576 of file structs.h.

3.7.2.10 IndexList

```
LIST C_const::IndexList
```

List of indices

Definition at line 1577 of file structs.h.

3.7.2.11 SetElementList

```
LIST C_const::SetElementList
```

List of all elements of all sets

Definition at line 1578 of file structs.h.

3.7.2.12 SetList

```
LIST C_const::SetList
```

List of the sets

Definition at line 1579 of file structs.h.

3.7.2.13 SymbolList

```
LIST C_const::SymbolList
```

List of the symbols and their properties

Definition at line 1580 of file structs.h.

3.7.2.14 VectorList

```
LIST C_const::VectorList
```

List of the vectors

Definition at line 1581 of file structs.h.

3.7.2.15 PotModDolList

```
LIST C_const::PotModDolList
```

Potentially changed dollars

Definition at line 1582 of file structs.h.

3.7.2.16 ModOptDolList

```
LIST C_const::ModOptDolList
```

Module Option Dollars list

Definition at line 1583 of file structs.h.

3.7.2.17 TableBaseList

```
LIST C_const::TableBaseList
```

TableBase list

Definition at line 1584 of file structs.h.

3.7.2.18 cbufList

```
LIST C_const::cbufList
```

List of compiler buffers

Definition at line 1588 of file structs.h.

3.7.2.19 AutoSymbolList

```
LIST C_const::AutoSymbolList
```

Definition at line 1592 of file structs.h.

3.7.2.20 AutoIndexList

```
LIST C_const::AutoIndexList
```

Definition at line 1593 of file structs.h.

3.7.2.21 AutoVectorList

```
LIST C_const::AutoVectorList
```

Definition at line 1594 of file structs.h.

3.7.2.22 AutoFunctionList

```
LIST C_const::AutoFunctionList
```

Definition at line 1595 of file structs.h.

3.7.2.23 autonames

```
NAMETREE* C_const::autonames
```

[D] Names in autodeclare

Definition at line 1596 of file structs.h.

3.7.2.24 Symbols

```
LIST* C_const::Symbols
```

Definition at line 1598 of file structs.h.

3.7.2.25 Indices

```
LIST* C_const::Indices
```

Definition at line 1600 of file structs.h.

3.7.2.26 Vectors

```
LIST* C_const::Vectors
```

Definition at line 1601 of file structs.h.

3.7.2.27 Functions

```
LIST* C_const::Functions
```

Definition at line 1602 of file structs.h.

3.7.2.28 activenames

```
NAMETREE** C_const::activenames
```

Definition at line 1603 of file structs.h.

3.7.2.29 Streams

```
STREAM* C_const::Streams
```

(C) Pointer for AutoDeclare statement. Points either to varnames or autonames. [D] The input streams.

Definition at line 1605 of file structs.h.

3.7.2.30 CurrentStream

```
STREAM* C_const::CurrentStream
```

(C) The current input stream. Streams are: do loop, file, prevariable. points into Streams memory.

Definition at line 1606 of file structs.h.

3.7.2.31 termstack

```
LONG* C_const::termstack
```

[D] Last term statement {offset}

Definition at line 1608 of file structs.h.

3.7.2.32 termsortstack

```
LONG* C_const::termsortstack
```

[D] Last sort statement {offset}

Definition at line 1609 of file structs.h.

3.7.2.33 cmod

```
UWORD* C_const::cmod
```

[D] Local setting of modulus. Pointer to value.

Definition at line 1610 of file structs.h.

3.7.2.34 powmod

```
UWORD* C_const::powmod
```

Local setting printing as powers. Points into cmod memory

Definition at line 1611 of file structs.h.

3.7.2.35 modpowers

```
UWORD* C_const::modpowers
```

[D] The conversion table for mod-> powers.

Definition at line 1612 of file structs.h.

3.7.2.36 halfmod

```
UWORD* C_const::halfmod
```

Definition at line 1613 of file structs.h.

3.7.2.37 ProtoType

```
WORD* C_const::ProtoType
```

Definition at line 1614 of file structs.h.

3.7.2.38 WildC

```
WORD* C_const::WildC
```

Definition at line 1615 of file structs.h.

3.7.2.39 IfHeap

```
LONG* C_const::IfHeap
```

[D] Keeps track of where to go in if

Definition at line 1616 of file structs.h.

3.7.2.40 IfCount

```
LONG* C_const::IfCount
```

[D] Keeps track of where to go in if

Definition at line 1617 of file structs.h.

3.7.2.41 IfStack

```
LONG* C_const::IfStack
```

Keeps track of where to go in if. Points into IfHeap-memory

Definition at line 1618 of file structs.h.

3.7.2.42 iBuffer

```
UBYTE* C_const::iBuffer
```

[D] Compiler input buffer

Definition at line 1619 of file structs.h.

3.7.2.43 iPointer

```
UBYTE* C_const::iPointer
```

Running pointer in the compiler input buffer

Definition at line 1620 of file structs.h.

3.7.2.44 iStop

```
UBYTE* C_const::iStop
```

Top of iBuffer

Definition at line 1621 of file structs.h.

3.7.2.45 LabelNames

```
UBYTE** C_const::LabelNames
```

[D] List of names in label statements

Definition at line 1622 of file structs.h.

3.7.2.46 FixIndices

```
WORD* C_const::FixIndices
```

[D] Buffer of fixed indices

Definition at line 1623 of file structs.h.

3.7.2.47 termsumcheck

```
WORD* C_const::termsumcheck
```

[D] Checking of nesting

Definition at line 1624 of file structs.h.

3.7.2.48 WildcardNames

```
UBYTE* C_const::WildcardNames
```

[D] Names of ?a variables

Definition at line 1625 of file structs.h.

3.7.2.49 Labels

```
int* C_const::Labels
```

Label information for during run. Pointer into LabelNames memory.

Definition at line 1626 of file structs.h.

3.7.2.50 tokens

```
SBYTE* C_const::tokens
```

[D] Array with tokens for tokenizer

Definition at line 1627 of file structs.h.

3.7.2.51 toptokens

```
SBYTE* C_const::toptokens
```

Top of tokens

Definition at line 1628 of file structs.h.

3.7.2.52 endoftokens

```
SBYTE* C_const::endoftokens
```

End of the actual tokens

Definition at line 1629 of file structs.h.

3.7.2.53 tokenarglevel

```
WORD* C_const::tokenarglevel
```

[D] Keeps track of function arguments

Definition at line 1630 of file structs.h.

3.7.2.54 modinverses

```
UWORD* C_const::modinverses
```

Definition at line 1631 of file structs.h.

3.7.2.55 Fortran90Kind

```
UBYTE* C_const::Fortran90Kind
```

Definition at line 1632 of file structs.h.

3.7.2.56 MultiBracketBuf

```
WORD** C_const::MultiBracketBuf
```

Definition at line 1633 of file structs.h.

3.7.2.57 extrasym

```
UBYTE* C_const::extrasym
```

Definition at line 1634 of file structs.h.

3.7.2.58 doloopstack

```
WORD* C_const::doloopstack
```

Definition at line 1635 of file structs.h.

3.7.2.59 doloopnest

```
WORD* C_const::doloopnest
```

Definition at line 1636 of file structs.h.

3.7.2.60 CheckpointRunAfter

```
char* C_const::CheckpointRunAfter
```

[D] Filename of script to be executed *before* creating the snapshot. =0 if no script shall be executed.

Definition at line 1637 of file structs.h.

3.7.2.61 CheckpointRunBefore

```
char* C_const::CheckpointRunBefore
```

[D] Filename of script to be executed *after* having created the snapshot. =0 if no script shall be executed.

Definition at line 1639 of file structs.h.

3.7.2.62 IfSumCheck

```
WORD* C_const::IfSumCheck
```

[D] Keeps track of if-nesting

Definition at line 1641 of file structs.h.

3.7.2.63 CommuteInSet

```
WORD* C_const::CommuteInSet
```

Definition at line 1642 of file structs.h.

3.7.2.64 TestValue

```
UBYTE* C_const::TestValue
```

Definition at line 1643 of file structs.h.

3.7.2.65 argstack

```
LONG C_const::argstack[MAXNEST]
```

Definition at line 1651 of file structs.h.

3.7.2.66 insidestack

```
LONG C_const::insidestack[MAXNEST]
```

Definition at line 1652 of file structs.h.

3.7.2.67 inexprstack

```
LONG C_const::inexprstack[MAXNEST]
```

Definition at line 1653 of file structs.h.

3.7.2.68 iBufferSize

```
LONG C_const::iBufferSize
```

Definition at line 1654 of file structs.h.

3.7.2.69 TransEname

```
LONG C_const::TransEname
```

Definition at line 1655 of file structs.h.

3.7.2.70 ProcessBucketSize

```
LONG C_const::ProcessBucketSize
```

Definition at line 1657 of file structs.h.

3.7.2.71 mProcessBucketSize

```
LONG C_const::mProcessBucketSize
```

Definition at line 1658 of file structs.h.

3.7.2.72 CModule

```
LONG C_const::CModule
```

Definition at line 1659 of file structs.h.

3.7.2.73 ThreadBucketSize

```
LONG C_const::ThreadBucketSize
```

Definition at line 1660 of file structs.h.

3.7.2.74 CheckpointStamp

```
LONG C_const::CheckpointStamp
```

Timestamp of the last created snapshot (set to Timer(0)).

Definition at line 1661 of file structs.h.

3.7.2.75 CheckpointInterval

```
LONG C_const::CheckpointInterval
```

Time interval in milliseconds for snapshots. =0 if snapshots shall be created at the end of *every* module.

Definition at line 1662 of file structs.h.

3.7.2.76 cbufnum

```
int C_const::cbufnum
```

Current compiler buffer

Definition at line 1664 of file structs.h.

3.7.2.77 AutoDeclareFlag

```
int C_const::AutoDeclareFlag
```

Definition at line 1665 of file structs.h.

3.7.2.78 NoShowInput

```
int C_const::NoShowInput
```

(C) Mode of looking for names. Set to NOAUTO (=0) or WITHAUTO (=2), cf. AutoDeclare statement

Definition at line 1667 of file structs.h.

3.7.2.79 ShortStats

```
int C_const::ShortStats
```

Definition at line 1668 of file structs.h.

3.7.2.80 compiletype

```
int C_const::compiletype
```

Definition at line 1669 of file structs.h.

3.7.2.81 firstconstindex

```
int C_const::firstconstindex
```

Definition at line 1670 of file structs.h.

3.7.2.82 insidefirst

```
int C_const::insidefirst
```

Definition at line 1671 of file structs.h.

3.7.2.83 minsidefirst

```
int C_const::minsidefirst
```

Definition at line 1672 of file structs.h.

3.7.2.84 wildflag

```
int C_const::wildflag
```

Definition at line 1673 of file structs.h.

3.7.2.85 NumLabels

```
int C_const::NumLabels
```

Definition at line 1674 of file structs.h.

3.7.2.86 MaxLabels

```
int C_const::MaxLabels
```

Definition at line 1675 of file structs.h.

3.7.2.87 lDefDim

```
int C_const::lDefDim
```

Definition at line 1676 of file structs.h.

3.7.2.88 lDefDim4

```
int C_const::lDefDim4
```

Definition at line 1677 of file structs.h.

3.7.2.89 NumWildcardNames

```
int C_const::NumWildcardNames
```

Definition at line 1678 of file structs.h.

3.7.2.90 WildcardBufferSize

```
int C_const::WildcardBufferSize
```

Definition at line 1679 of file structs.h.

3.7.2.91 MaxIf

```
int C_const::MaxIf
```

Definition at line 1680 of file structs.h.

3.7.2.92 NumStreams

```
int C_const::NumStreams
```

Definition at line 1681 of file structs.h.

3.7.2.93 MaxNumStreams

```
int C_const::MaxNumStreams
```

Definition at line 1682 of file structs.h.

3.7.2.94 firstctypemessage

```
int C_const::firstctypemessage
```

Definition at line 1683 of file structs.h.

3.7.2.95 tablecheck

```
int C_const::tablecheck
```

Definition at line 1684 of file structs.h.

3.7.2.96 idoption

```
int C_const::idoption
```

Definition at line 1685 of file structs.h.

3.7.2.97 BottomLevel

```
int C_const::BottomLevel
```

Definition at line 1686 of file structs.h.

3.7.2.98 CompileLevel

```
int C_const::CompileLevel
```

Definition at line 1687 of file structs.h.

3.7.2.99 TokensWriteFlag

```
int C_const::TokensWriteFlag
```

Definition at line 1688 of file structs.h.

3.7.2.100 UnsureDollarMode

```
int C_const::UnsureDollarMode
```

Definition at line 1689 of file structs.h.

3.7.2.101 outsidefun

```
int C_const::outsidefun
```

Definition at line 1690 of file structs.h.

3.7.2.102 funpowers

```
int C_const::funpowers
```

Definition at line 1691 of file structs.h.

3.7.2.103 WarnFlag

```
int C_const::WarnFlag
```

Definition at line 1692 of file structs.h.

3.7.2.104 StatsFlag

```
int C_const::StatsFlag
```

Definition at line 1693 of file structs.h.

3.7.2.105 NamesFlag

```
int C_const::NamesFlag
```

Definition at line 1694 of file structs.h.

3.7.2.106 CodesFlag

```
int C_const::CodesFlag
```

Definition at line 1695 of file structs.h.

3.7.2.107 SetupFlag

```
int C_const::SetupFlag
```

Definition at line 1696 of file structs.h.

3.7.2.108 SortType

```
int C_const::SortType
```

Definition at line 1697 of file structs.h.

3.7.2.109 lSortType

```
int C_const::lSortType
```

Definition at line 1698 of file structs.h.

3.7.2.110 ThreadStats

```
int C_const::ThreadStats
```

Definition at line 1699 of file structs.h.

3.7.2.111 FinalStats

```
int C_const::FinalStats
```

Definition at line 1700 of file structs.h.

3.7.2.112 OldParallelStats

```
int C_const::OldParallelStats
```

Definition at line 1701 of file structs.h.

3.7.2.113 ThreadsFlag

```
int C_const::ThreadsFlag
```

Definition at line 1702 of file structs.h.

3.7.2.114 ThreadBalancing

```
int C_const::ThreadBalancing
```

Definition at line 1703 of file structs.h.

3.7.2.115 ThreadSortFileSynch

```
int C_const::ThreadSortFileSynch
```

Definition at line 1704 of file structs.h.

3.7.2.116 ProcessStats

```
int C_const::ProcessStats
```

Definition at line 1705 of file structs.h.

3.7.2.117 BracketNormalize

```
int C_const::BracketNormalize
```

Definition at line 1706 of file structs.h.

3.7.2.118 maxtermlevel

```
int C_const::maxtermlevel
```

Definition at line 1707 of file structs.h.

3.7.2.119 dumnumflag

```
int C_const::dumnumflag
```

Definition at line 1708 of file structs.h.

3.7.2.120 bracketindexflag

```
int C_const::bracketindexflag
```

Definition at line 1709 of file structs.h.

3.7.2.121 parallelflag

```
int C_const::parallelflag
```

Definition at line 1710 of file structs.h.

3.7.2.122 mparallelflag

```
int C_const::mparallelflag
```

Definition at line 1711 of file structs.h.

3.7.2.123 inparallelflag

```
int C_const::inparallelflag
```

Definition at line 1712 of file structs.h.

3.7.2.124 partodoflag

```
int C_const::partodoflag
```

Definition at line 1713 of file structs.h.

3.7.2.125 properorderflag

```
int C_const::properorderflag
```

Definition at line 1714 of file structs.h.

3.7.2.126 vetofilling

```
int C_const::vetofilling
```

Definition at line 1715 of file structs.h.

3.7.2.127 tablefilling

```
int C_const::tablefilling
```

Definition at line 1716 of file structs.h.

3.7.2.128 vetotablebasefill

```
int C_const::vetotablebasefill
```

Definition at line 1717 of file structs.h.

3.7.2.129 exprfillwarning

```
int C_const::exprfillwarning
```

Definition at line 1718 of file structs.h.

3.7.2.130 lhdollarflag

```
int C_const::lhdollarflag
```

Definition at line 1719 of file structs.h.

3.7.2.131 NoCompress

```
int C_const::NoCompress
```

Definition at line 1720 of file structs.h.

3.7.2.132 IsFortran90

```
int C_const::IsFortran90
```

Definition at line 1721 of file structs.h.

3.7.2.133 MultiBracketLevels

```
int C_const::MultiBracketLevels
```

Definition at line 1722 of file structs.h.

3.7.2.134 topolynomialflag

```
int C_const::topolynomialflag
```

Definition at line 1723 of file structs.h.

3.7.2.135 ffbufnum

```
int C_const::ffbufnum
```

Definition at line 1724 of file structs.h.

3.7.2.136 OldFactArgFlag

```
int C_const::OldFactArgFlag
```

Definition at line 1725 of file structs.h.

3.7.2.137 MemDebugFlag

```
int C_const::MemDebugFlag
```

Definition at line 1726 of file structs.h.

3.7.2.138 OldGCDflag

```
int C_const::OldGCDflag
```

Definition at line 1727 of file structs.h.

3.7.2.139 WTimeStatsFlag

```
int C_const::WTimeStatsFlag
```

Definition at line 1728 of file structs.h.

3.7.2.140 doloopstacksize

```
int C_const::doloopstacksize
```

Definition at line 1729 of file structs.h.

3.7.2.141 dolooplevel

```
int C_const::dolooplevel
```

Definition at line 1730 of file structs.h.

3.7.2.142 CheckpointFlag

```
int C_const::CheckpointFlag
```

Tells preprocessor whether checkpoint code must executed. -1 : do recovery from snapshot, set by command line option; 0 : do nothing; 1 : create snapshots, set by On checkpoint statement

Definition at line 1731 of file structs.h.

3.7.2.143 SizeCommuteInSet

```
int C_const::SizeCommuteInSet
```

Definition at line 1735 of file structs.h.

3.7.2.144 origin

```
int C_const::origin
```

Definition at line 1740 of file structs.h.

3.7.2.145 vectorlikeLHS

```
int C_const::vectorlikeLHS
```

Definition at line 1741 of file structs.h.

3.7.2.146 argsumcheck

```
WORD C_const::argsumcheck[MAXNEST]
```

Definition at line 1742 of file structs.h.

3.7.2.147 insidesumcheck

```
WORD C_const::insidesumcheck[MAXNEST]
```

Definition at line 1743 of file structs.h.

3.7.2.148 inexprsumcheck

```
WORD C_const::inexprsumcheck[MAXNEST]
```

Definition at line 1744 of file structs.h.

3.7.2.149 RepSumCheck

```
WORD C_const::RepSumCheck[MAXREPEAT]
```

Definition at line 1745 of file structs.h.

3.7.2.150 lUniTrace

```
WORD C_const::lUniTrace[4]
```

Definition at line 1746 of file structs.h.

3.7.2.151 RepLevel

```
WORD C_const::RepLevel
```

Definition at line 1747 of file structs.h.

3.7.2.152 arglevel

```
WORD C_const::arglevel
```

Definition at line 1748 of file structs.h.

3.7.2.153 insidelevel

```
WORD C_const::insidelevel
```

Definition at line 1749 of file structs.h.

3.7.2.154 inexprlevel

```
WORD C_const::inexprlevel
```

Definition at line 1750 of file structs.h.

3.7.2.155 termlevel

```
WORD C_const::termlevel
```

Definition at line 1751 of file structs.h.

3.7.2.156 MustTestTable

```
WORD C_const::MustTestTable
```

Definition at line 1752 of file structs.h.

3.7.2.157 DumNum

```
WORD C_const::DumNum
```

Definition at line 1753 of file structs.h.

3.7.2.158 ncmod

```
WORD C_const::ncmod
```

Definition at line 1754 of file structs.h.

3.7.2.159 npowmod

```
WORD C_const::npowmod
```

Definition at line 1755 of file structs.h.

3.7.2.160 modmode

```
WORD C_const::modmode
```

```
WORD C_const::LogHandle
```

Definition at line 1771 of file structs.h.

3.7.2.176 LineLength

```
WORD C_const::LineLength
```

Definition at line 1772 of file structs.h.

3.7.2.177 StoreHandle

```
WORD C_const::StoreHandle
```

Definition at line 1773 of file structs.h.

3.7.2.178 HideLevel

```
WORD C_const::HideLevel
```

Definition at line 1774 of file structs.h.

3.7.2.179 lPolyFun

```
WORD C_const::lPolyFun
```

Definition at line 1775 of file structs.h.

3.7.2.180 lPolyFunInv

```
WORD C_const::lPolyFunInv
```

Definition at line 1776 of file structs.h.

3.7.2.181 lPolyFunType

```
WORD C_const::lPolyFunType
```

Definition at line 1777 of file structs.h.

3.7.2.182 lPolyFunExp

```
WORD C_const::lPolyFunExp
```

Definition at line 1778 of file structs.h.

3.7.2.183 lPolyFunVar

```
WORD C_const::lPolyFunVar
```

Definition at line 1779 of file structs.h.

3.7.2.184 lPolyFunPow

```
WORD C_const::lPolyFunPow
```

Definition at line 1780 of file structs.h.

3.7.2.185 SymChangeFlag

```
WORD C_const::SymChangeFlag
```

Definition at line 1781 of file structs.h.

3.7.2.186 CollectPercentage

```
WORD C_const::CollectPercentage
```

Definition at line 1782 of file structs.h.

3.7.2.187 ShortStatsMax

```
WORD C_const::ShortStatsMax
```

Definition at line 1783 of file structs.h.

3.7.2.188 extrasymbols

```
WORD C_const::extrasymbols
```

Definition at line 1784 of file structs.h.

3.7.2.189 PolyRatFunChanged

```
WORD C_const::PolyRatFunChanged
```

Definition at line 1785 of file structs.h.

3.7.2.190 ToBeInFactors

```
WORD C_const::ToBeInFactors
```

Definition at line 1786 of file structs.h.

3.7.2.191 InnerTest

```
WORD C_const::InnerTest
```

Definition at line 1787 of file structs.h.

3.7.2.192 Commercial

```
UBYTE C_const::Commercial[COMMERCIALSIZE+2]
```

Definition at line 1791 of file structs.h.

3.7.2.193 debugFlags

```
UBYTE C_const::debugFlags[MAXFLAGS+2]
```

Definition at line 1792 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.8 CbUf Struct Reference

```
#include <structs.h>
```

3.8.1 Detailed Description

The CBUF struct is used by the compiler. It is a compiler buffer of which since version 3.0 there can be many.

Definition at line 921 of file structs.h.

3.8.2 Field Documentation

3.8.2.1 Buffer

```
WORD* CbUf::Buffer
```

[D] Size in BufferSize

Definition at line 922 of file structs.h.

Referenced by CleanupArgCache(), clearcbuf(), DoubleCbuffer(), finishcbuf(), inicbufs(), PF_BroadcastCBuf(), and Processor().

3.8.2.2 Top

```
WORD* CbUf::Top
```

pointer to the end of the Buffer memory

Definition at line 923 of file structs.h.

Referenced by AddNtoC(), AddNtoL(), DoubleCbuffer(), finishcbuf(), inicbufs(), PF_BroadcastCBuf(), and TestSub().

3.8.2.3 Pointer

```
WORD* CbUf::Pointer
```

pointer into the Buffer memory

Definition at line 924 of file structs.h.

Referenced by AddLHS(), AddNtoC(), AddNtoL(), AddRHS(), CleanupArgCache(), clearcbuf(), DoubleCbuffer(), finishcbuf(), Generator(), inicbufs(), PF_BroadcastCBuf(), Processor(), and TestSub().

3.8.2.4 lhs

```
WORD** CbUf::lhs
```

[D] Size in maxlhs. list of pointers into Buffer.

Definition at line 925 of file structs.h.

Referenced by AddLHS(), DoubleCbuffer(), finishcbuf(), Generator(), inicbufs(), PF_BroadcastCBuf(), Processor(), and TestMatch().

3.8.2.5 rhs

```
WORD** CbUf::rhs
```

[D] Size in maxrhs. list of pointers into Buffer.

Definition at line 926 of file structs.h.

Referenced by AddRHS(), CleanupArgCache(), clearcbuf(), DoubleCbuffer(), finishcbuf(), Generator(), inicbufs(), IniFbuffer(), PF_BroadcastCBuf(), Processor(), and TestSub().

3.8.2.6 CanCommu

```
LONG* CbUf::CanCommu
```

points into rhs memory behind WORD∗ area.

Definition at line 927 of file structs.h.

Referenced by AddRHS(), finishcbuf(), inicbufs(), IniFbuffer(), PF_BroadcastCBuf(), and TestSub().

3.8.2.7 NumTerms

```
LONG* CbUf::NumTerms
```

points into rhs memory behind CanCommu area

Definition at line 928 of file structs.h.

Referenced by AddRHS(), finishcbuf(), inicbufs(), IniFbuffer(), and PF_BroadcastCBuf().

3.8.2.8 numdum

```
WORD* CbUf::numdum
```

points into rhs memory behind NumTerms

Definition at line 929 of file structs.h.

Referenced by AddRHS(), inicbufs(), IniFbuffer(), and PF_BroadcastCBuf().

3.8.2.9 dimension

```
WORD* CbUf::dimension
```

points into rhs memory behind numdum

Definition at line 930 of file structs.h.

Referenced by AddRHS(), inicbufs(), IniFbuffer(), and PF_BroadcastCBuf().

3.8.2.10 boomlijst

```
COMPTREE* CbUf::boomlijst
```

[D] Number elements in MaxTreeSize

Definition at line 931 of file structs.h.

Referenced by CleanupArgCache(), clearcbuf(), finishcbuf(), inicbufs(), IniFbuffer(), and PF_BroadcastCBuf().

3.8.2.11 BufferSize

```
LONG CbUf::BufferSize
```

Number of allocated WORD's in Buffer

Definition at line 932 of file structs.h.

Referenced by DoubleCbuffer(), finishcbuf(), inicbufs(), and PF_BroadcastCBuf().

3.8.2.12 numlhs

```
int CbUf::numlhs
```

Definition at line 933 of file structs.h.

3.8.2.13 numrhs

```
int CbUf::numrhs
```

Definition at line 934 of file structs.h.

3.8.2.14 maxlhs

```
int CbUf::maxlhs
```

Definition at line 935 of file structs.h.

3.8.2.15 maxrhs

```
int CbUf::maxrhs
```

Definition at line 936 of file structs.h.

3.8.2.16 mnumlhs

```
int CbUf::mnumlhs
```

Definition at line 937 of file structs.h.

3.8.2.17 mnumrhs

```
int CbUf::mnumrhs
```

Definition at line 938 of file structs.h.

3.8.2.18 numtree

```
int CbUf::numtree
```

Definition at line 939 of file structs.h.

3.8.2.19 rootnum

```
int CbUf::rootnum
```

Definition at line 940 of file structs.h.

3.8.2.20 MaxTreeSize

```
int CbUf::MaxTreeSize
```

Definition at line 941 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.9 ChAnNeL Struct Reference

```
#include <structs.h>
```

Data Fields

- char * name
- int handle

3.9.1 Detailed Description

When we read input from text files we have to remember not only their handle but also their name. This is needed for error messages. Hence we call such a file a channel and reserve a struct of type CHANNEL to allow to lay this link.

Definition at line 952 of file structs.h.

3.9.2 Field Documentation

3.9.2.1 name

```
char* ChAnNeL::name
```

[D] Name of the channel

Definition at line 953 of file structs.h.

3.9.2.2 handle

```
int ChAnNeL::handle
```

File handle

Definition at line 954 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.10 COST Struct Reference

Data Fields

- LONG add
- LONG mul
- LONG div
- LONG pow

3.10.1 Detailed Description

Definition at line 1224 of file structs.h.

3.10.2 Field Documentation

3.10.2.1 add

```
LONG COST::add
```

Definition at line 1225 of file structs.h.

3.10.2.2 mul

```
LONG COST::mul
```

Definition at line 1226 of file structs.h.

3.10.2.3 div

```
LONG COST::div
```

Definition at line 1227 of file structs.h.

3.10.2.4 pow

```
LONG COST::pow
```

Definition at line 1228 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.11 dbase Struct Reference

Collaboration diagram for dbase:

Data Fields

- INIINFO info
- MLONG mode
- MLONG tablenamessize
- MLONG topnumber
- MLONG tablenamefill
- INDEXBLOCK ** iblocks
- NAMESBLOCK ** nblocks
- FILE * handle
- char * name
- char * fullname
- char * tablenames

3.11.1 Detailed Description

Definition at line 120 of file minos.h.

3.11.2 Field Documentation

3.11.2.1 info

```
INIINFO dbase::info
```

Definition at line 121 of file minos.h.

3.11.2.2 mode

```
MLONG dbase::mode
```

Definition at line 122 of file minos.h.

3.11.2.3 tablenamessize

```
MLONG dbase::tablenamessize
```

Definition at line 123 of file minos.h.

3.11.2.4 topnumber

```
MLONG dbase::topnumber
```

Definition at line 124 of file minos.h.

3.11.2.5 tablenamefill

```
MLONG dbase::tablenamefill
```

Definition at line 125 of file minos.h.

3.11.2.6 iblocks

```
INDEXBLOCK** dbase::iblocks
```

Definition at line 126 of file minos.h.

3.11.2.7 nblocks

```
NAMESBLOCK** dbase::nblocks
```

Definition at line 127 of file minos.h.

3.11.2.8 handle

```
FILE* dbase::handle
```

Definition at line 128 of file minos.h.

3.11.2.9 name

```
char* dbase::name
```

Definition at line 129 of file minos.h.

3.11.2.10 fullname

```
char* dbase::fullname
```

Definition at line 130 of file minos.h.

3.11.2.11 tablenames

```
char* dbase::tablenames
```

Definition at line 131 of file minos.h.

The documentation for this struct was generated from the following file:

- minos.h

3.12 DICTIONARY Struct Reference

Collaboration diagram for DICTIONARY:

Data Fields

- DICTIONARY_ELEMENT ** elements
- UBYTE * name
- int sizeelements
- int numelements
- int numbers
- int variables
- int characters
- int funwith
- int gnumelements
- int ranges

3.12.1 Detailed Description

Definition at line 1290 of file structs.h.

3.12.2 Field Documentation

3.12.2.1 elements

```
DICTIONARY_ELEMENT** DICTIONARY::elements
```

Definition at line 1291 of file structs.h.

3.12.2.2 name

```
UBYTE* DICTIONARY::name
```

Definition at line 1292 of file structs.h.

3.12.2.3 sizeelements

```
int DICTIONARY::sizeelements
```

Definition at line 1293 of file structs.h.

3.12.2.4 numelements

```
int DICTIONARY::numelements
```

Definition at line 1294 of file structs.h.

3.12.2.5 numbers

```
int DICTIONARY::numbers
```

Definition at line 1295 of file structs.h.

3.12.2.6 variables

```
int DICTIONARY::variables
```

Definition at line 1296 of file structs.h.

3.12.2.7 characters

```
int DICTIONARY::characters
```

Definition at line 1297 of file structs.h.

3.12.2.8 funwith

```
int DICTIONARY::funwith
```

Definition at line 1298 of file structs.h.

3.12.2.9 gnumelements

```
int DICTIONARY::gnumelements
```

Definition at line 1299 of file structs.h.

3.12.2.10 ranges

```
int DICTIONARY::ranges
```

Definition at line 1300 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.13 DICTIONARY_ELEMENT Struct Reference

Data Fields

- WORD * lhs
- WORD * rhs
- int type
- int size

3.13.1 Detailed Description

Definition at line 1283 of file structs.h.

3.13.2 Field Documentation

3.13.2.1 lhs

```
WORD* DICTIONARY_ELEMENT::lhs
```

Definition at line 1284 of file structs.h.

3.13.2.2 rhs

```
WORD* DICTIONARY_ELEMENT::rhs
```

Definition at line 1285 of file structs.h.

3.13.2.3 type

```
int DICTIONARY_ELEMENT::type
```

Definition at line 1286 of file structs.h.

3.13.2.4 size

```
int DICTIONARY_ELEMENT::size
```

Definition at line 1287 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.14 DiStRiBuTe Struct Reference

```
#include <structs.h>
```

Data Fields

- WORD * obj1
- WORD * obj2
- WORD * out
- WORD sign
- WORD n1
- WORD n2
- WORD n
- WORD cycle [MAXMATCH]

3.14.1 Detailed Description

The struct DISTRIBUTE is used to help the pattern matcher when matching antisymmetric tensors.

Definition at line 1032 of file structs.h.

3.14.2 Field Documentation

3.14.2.1 obj1

```
WORD* DiStRiBuTe::obj1
```

Definition at line 1033 of file structs.h.

3.14.2.2 obj2

```
WORD* DiStRiBuTe::obj2
```

Definition at line 1034 of file structs.h.

3.14.2.3 out

```
WORD* DiStRiBuTe::out
```

Definition at line 1035 of file structs.h.

3.14.2.4 sign

```
WORD DiStRiBuTe::sign
```

Definition at line 1036 of file structs.h.

3.14.2.5 n1

```
WORD DiStRiBuTe::n1
```

Definition at line 1037 of file structs.h.

3.14.2.6 n2

```
WORD DiStRiBuTe::n2
```

Definition at line 1038 of file structs.h.

3.14.2.7 n

```
WORD DiStRiBuTe::n
```

Definition at line 1039 of file structs.h.

3.14.2.8 cycle

```
WORD DiStRiBuTe::cycle[MAXMATCH]
```

Definition at line 1040 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.15 dollar_buf Struct Reference

3.15.1 Detailed Description

Definition at line 2468 of file parallel.c.

The documentation for this struct was generated from the following file:

- parallel.c

3.16 DoLlArS Struct Reference

Collaboration diagram for DoLlArS:

Data Fields

- WORD * where
- FACDOLLAR * factors
- LONG size
- LONG name
- WORD type
- WORD node
- WORD index
- WORD zero
- WORD numdummies
- WORD nfactors

3.16.1 Detailed Description

Definition at line 515 of file structs.h.

3.16.2 Field Documentation

3.16.2.1 where

```
WORD* DoLlArS::where
```

Definition at line 516 of file structs.h.

3.17 DoLoOp Struct Reference

```
#include <structs.h>
```

Collaboration diagram for DoLoOp:

Data Fields

- PRELOAD p
- UBYTE * name
- UBYTE * vars
- UBYTE * contents
- UBYTE * dollarname
- LONG startlinenumber
- LONG firstnum
- LONG lastnum
- LONG incnum
- int type
- int NoShowInput
- int errorsinloop
- int firstloopcall
- WORD firstdollar
- WORD lastdollar
- WORD incdollar
- WORD NumPreTypes
- WORD PreIfLevel
- WORD PreSwitchLevel

3.17.1 Detailed Description

Each preprocessor do loop has a struct of type DOLOOP to keep track of all relevant parameters like where the beginning of the loop is, what the boundaries, increment and value of the loop parameter are, etc. Also we keep the whole loop inside a buffer of type PRELOAD

Definition at line 835 of file structs.h.

3.17.2 Field Documentation

3.17.2.1 p

```
PRELOAD DoLoOp::p
```

size, name and buffer

Definition at line 836 of file structs.h.

3.17.2.2 name

```
UBYTE* DoLoOp::name
```

pointer into PRELOAD buffer

Definition at line 837 of file structs.h.

3.17.2.3 vars

```
UBYTE* DoLoOp::vars
```

Definition at line 838 of file structs.h.

3.17.2.4 contents

```
UBYTE* DoLoOp::contents
```

Definition at line 839 of file structs.h.

3.17.2.5 dollarname

```
UBYTE* DoLoOp::dollarname
```

For loop over terms in expression. Allocated with Malloc1()

Definition at line 840 of file structs.h.

- char * name
- ULONG numblocks
- ULONG inbuffer
- LONG POsize
- int handle
- int active

3.22.1 Detailed Description

The type FILEHANDLE is the struct that controls all relevant information of a file, whether it is open or not. The file may even not yet exist. There is a system of caches (PObuffer) and as long as the information to be written still fits inside the cache the file may never be created. There are variables that can store information about different types of files, like scratch files or sort files. Depending on what is available in the system we may also have information about gzip compression (currently sort file only) or locks (TFORM).

Definition at line 620 of file structs.h.

3.22.2 Field Documentation

3.24 FiLeInDeX Struct Reference

```
#include <structs.h>
```

Collaboration diagram for FiLeInDeX:

Data Fields

- POSITION next
- POSITION number
- INDEXENTRY expression [INFILEINDEX]
- SBYTE empty [EMPTYININDEX]

3.24.1 Detailed Description

Defines the structure of a file index in store-files and save-files.

It contains several entries (see struct InDeXeNtRy) up to a maximum of INFILEINDEX.

The variable number has been made of type POSITION to avoid padding problems with some types of computers/↩ OS and keep system independence of the .sav files.

This struct is always 512 bytes long.

Definition at line 137 of file structs.h.

3.24.2 Field Documentation

3.24.2.1 next

```
POSITION FiLeInDeX::next
```

Position of next FILEINDEX if any

Definition at line 138 of file structs.h.

Referenced by ReadSaveIndex().

3.24.2.2 number

```
POSITION FiLeInDeX::number
```

Number of used entries in this index

Definition at line 139 of file structs.h.

Referenced by ReadSaveIndex().

3.24.2.3 expression

```
INDEXENTRY FiLeInDeX::expression[INFILEINDEX]
```

File index entries

Definition at line 140 of file structs.h.

3.24.2.4 empty

```
SBYTE FiLeInDeX::empty[EMPTYININDEX]
```

Padding to 512 bytes

Definition at line 141 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.25 FixedGlobals Struct Reference

```
#include <structs.h>
```

Data Fields

- WCN Operation [8]
- WCN2 OperaFind [6]
- char * VarType [10]
- char * ExprStat [21]
- char * FunNam [2]
- char * swmes [3]
- char * fname
- char * fname2
- UBYTE * s_one
- WORD fnamebase
- WORD fname2base
- UINT cTable [256]

3.25.1 Detailed Description

The FIXEDGLOBALS struct is an anachronism. It started as the struct with global variables that needed initialization. It contains the elements Operation and OperaFind which define a very early way of automatically jumping to the proper operation. We find the results of it in parts of the file opera.c Later operations were treated differently in a more transparent way. We never changed the existing code. The most important part is currently the cTable which is used intensively in the compiler.

Definition at line 2438 of file structs.h.

3.25.2 Field Documentation

3.25.2.1 Operation

```

- LONG name
- WORD commute
- WORD complex
- WORD number
- WORD flags
- WORD spec
- WORD symmetric
- WORD node
- WORD namesize
- WORD dimension
- WORD maxnumargs
- WORD minnumargs

3.28.1 Detailed Description

Contains all information about a function. Also used for tables. It is used in the LIST elements of AC.

Definition at line 463 of file structs.h.

3.28.2 Field Documentation

3.28.2.1 tabl

`TABLES FuNcTiOn::tabl`

Used if redefined as table. != 0 if function is a table

Definition at line 464 of file structs.h.

3.28.2.2 symminfo

`LONG FuNcTiOn::symminfo`

Info regarding symm properties offset in buffer

Definition at line 465 of file structs.h.

3.28.2.3 name

`LONG FuNcTiOn::name`

Location in namebuffer of NAMETREE

Definition at line 466 of file structs.h.

Referenced by StartVariables().

3.28.2.4 commute

`WORD FuNcTiOn::commute`

Commutation properties

Definition at line 467 of file structs.h.

3.28.2.5 complex

`WORD FuNcTiOn::complex`

Properties under complex conjugation

Definition at line 468 of file structs.h.

3.28.2.6 number

```
WORD FuNcTiOn::number
```

Number when stored in file

Definition at line 469 of file structs.h.

Referenced by ReadSaveIndex().

3.28.2.7 flags

```
WORD FuNcTiOn::flags
```

Used to indicate usage when storing

Definition at line 470 of file structs.h.

3.28.2.8 spec

```
WORD FuNcTiOn::spec
```

Regular, Tensor, etc. See FunSpecs.

Definition at line 471 of file structs.h.

Referenced by ReadSaveVariables().

3.28.2.9 symmetric

```
WORD FuNcTiOn::symmetric
```

0 if symmetric properties

Definition at line 472 of file structs.h.

Referenced by StartVariables().

3.28.2.10 node

```

3.37 LIST Struct Reference

```
#include <structs.h>
```

Data Fields

- void * lijst
- char * message
- int num
- int maxnum
- int size
- int numglobal
- int numtemp
- int numclear

3.37.1 Detailed Description

Much information is stored in arrays of which we can double the size if the array proves to be too small. Such arrays are controled by a variable of type LIST. The routines that expand the lists are in the file tools.c

Definition at line 204 of file structs.h.

3.37.2 Field Documentation

3.37.2.1 lijst

```
void* LIST::lijst
```

[D] Holds space for "maxnum" elements of size "size" each

Definition at line 205 of file structs.h.

3.37.2.2 message

```
char* LIST::message
```

Text for Malloc1 when allocating lijst. Set to constant string.

Definition at line 206 of file structs.h.

3.37.2.3 num

```
int LIST::num
```

Number of elements in lijst.

Definition at line 207 of file structs.h.

3.37.2.4 maxnum

```
int LIST::maxnum
```

Maximum number of elements in lijst.

Definition at line 208 of file structs.h.

3.37.2.5 size

```
int LIST::size
```

Size of one element in lijst.

Definition at line 209 of file structs.h.

3.37.2.6 numglobal

```
int LIST::numglobal
```

Marker for position when .global is executed.

Definition at line 210 of file structs.h.

3.37.2.7 numtemp

```
int LIST::numtemp
```

At the moment only needed for sets and setstore.

Definition at line 211 of file structs.h.

3.37.2.8 numclear

```
int LIST::numclear
```

Only for the clear instruction.

Definition at line 212 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.38 longMultiStruct Struct Reference

Collaboration diagram for longMultiStruct:

3.39.1 Detailed Description

The M_const struct is part of the global data and resides in the ALLGLOBALS struct A under the name #M. We see it used with the macro AM as in AM.S0. It contains global settings at startup or .clear.

Definition at line 1316 of file structs.h.

3.39.2 Field Documentation

3.39.2.1 zeropos

```
POSITION M_const::zeropos
```

Definition at line 1317 of file structs.h.

3.39.2.2 S0

```
SORTING* M_const::S0
```

[D] The main sort buffer

Definition at line 1318 of file structs.h.

3.39.2.3 gcmod

```
UWORD* M_const::gcmod
```

Global setting of modulus. Uses AC.cmod's memory

Definition at line 1319 of file structs.h.

3.39.2.4 gpowmod

```
UWORD* M_const::gpowmod
```

Global setting printing as powers. Uses AC.cmod's memory

Definition at line 1320 of file structs.h.

3.39.2.5 TempDir

```
UBYTE* M_const::TempDir
```

Definition at line 1321 of file structs.h.

3.39.2.6 TempSortDir

```
UBYTE* M_const::TempSortDir
```

Definition at line 1322 of file structs.h.

3.39.2.7 IncDir

```
UBYTE* M_const::IncDir
```

Definition at line 1323 of file structs.h.

3.39.2.8 InputFileName

```
UBYTE* M_const::InputFileName
```

Definition at line 1324 of file structs.h.

3.39.2.9 LogFileName

```
UBYTE* M_const::LogFileName
```

Definition at line 1325 of file structs.h.

3.39.2.10 OutBuffer

```
UBYTE* M_const::OutBuffer
```

Definition at line 1326 of file structs.h.

3.39.2.11 Path

```
UBYTE* M_const::Path
```

Definition at line 1327 of file structs.h.

3.39.2.12 SetupDir

```
UBYTE* M_const::SetupDir
```

Definition at line 1328 of file structs.h.

3.39.2.13 SetupFile

```
UBYTE* M_const::SetupFile
```

Definition at line 1329 of file structs.h.

3.39.2.14 gFortran90Kind

```
UBYTE* M_const::gFortran90Kind
```

Definition at line 1330 of file structs.h.

3.39.2.15 gextrasym

```
UBYTE* M_const::gextrasym
```

Definition at line 1331 of file structs.h.

3.39.2.16 ggextrasym

```
UBYTE* M_const::ggextrasym
```

Definition at line 1332 of file structs.h.

3.39.2.17 oldnumextrasymbols

```
UBYTE* M_const::oldnumextrasymbols
```

Definition at line 1333 of file structs.h.

3.39.2.18 SpectatorFiles

```
SPECTATOR* M_const::SpectatorFiles
```

Definition at line 1334 of file structs.h.

3.39.2.19 MaxTer

```
LONG M_const::MaxTer
```

Definition at line 1342 of file structs.h.

3.39.2.20 CompressSize

```
LONG M_const::CompressSize
```

Definition at line 1343 of file structs.h.

3.39.2.21 ScratSize

```
LONG M_const::ScratSize
```

Definition at line 1344 of file structs.h.

3.39.2.22 HideSize

```
LONG M_const::HideSize
```

Definition at line 1345 of file structs.h.

3.39.2.23 SizeStoreCache

```
LONG M_const::SizeStoreCache
```

Definition at line 1346 of file structs.h.

3.39.2.24 MaxStreamSize

```
LONG M_const::MaxStreamSize
```

Definition at line 1347 of file structs.h.

3.39.2.25 SIOsize

```
LONG M_const::SIOsize
```

Definition at line 1348 of file structs.h.

3.39.2.26 SLargeSize

```
LONG M_const::SLargeSize
```

Definition at line 1349 of file structs.h.

3.39.2.27 SSmallEsize

```
LONG M_const::SSmallEsize
```

Definition at line 1350 of file structs.h.

3.39.2.28 SSmallSize

```
LONG M_const::SSmallSize
```

Definition at line 1351 of file structs.h.

3.39.2.29 STermsInSmall

```
LONG M_const::STermsInSmall
```

Definition at line 1352 of file structs.h.

3.39.2.30 MaxBracketBufferSize

```
LONG M_const::MaxBracketBufferSize
```

Definition at line 1353 of file structs.h.

3.39.2.31 hProcessBucketSize

```
LONG M_const::hProcessBucketSize
```

Definition at line 1354 of file structs.h.

3.39.2.32 gProcessBucketSize

```

```

Definition at line 1355 of file structs.h.

3.39.2.33 shmWinSize

```
LONG M_const::shmWinSize
```

Definition at line 1356 of file structs.h.

3.39.2.34 OldChildTime

```
LONG M_const::OldChildTime
```

Definition at line 1357 of file structs.h.

3.39.2.35 OldSecTime

```
LONG M_const::OldSecTime
```

Definition at line 1358 of file structs.h.

3.39.2.36 OldMilliTime

```
LONG M_const::OldMilliTime
```

Definition at line 1359 of file structs.h.

3.39.2.37 WorkSize

```
LONG M_const::WorkSize
```

Definition at line 1360 of file structs.h.

3.39.2.38 gThreadBucketSize

```
LONG M_const::gThreadBucketSize
```

Definition at line 1361 of file structs.h.

3.39.2.39 ggThreadBucketSize

```
LONG M_const::ggThreadBucketSize
```

Definition at line 1362 of file structs.h.

3.39.2.40 SumTime

```
LONG M_const::SumTime
```

Definition at line 1363 of file structs.h.

3.39.2.41 SpectatorSize

```
LONG M_const::SpectatorSize
```

Definition at line 1364 of file structs.h.

3.39.2.42 FileOnlyFlag

```
int M_const::FileOnlyFlag
```

Definition at line 1365 of file structs.h.

3.39.2.43 Interact

```
int M_const::Interact
```

Definition at line 1366 of file structs.h.

3.39.2.44 MaxParLevel

```
int M_const::MaxParLevel
```

Definition at line 1367 of file structs.h.

3.39.2.45 OutBufSize

```
int M_const::OutBufSize
```

Definition at line 1368 of file structs.h.

3.39.2.46 SMaxFpatches

```
int M_const::SMaxFpatches
```

Definition at line 1369 of file structs.h.

3.39.2.47 SMaxPatches

```
int M_const::SMaxPatches
```

Definition at line 1370 of file structs.h.

3.39.2.48 StdOut

```
int M_const::StdOut
```

Definition at line 1371 of file structs.h.

3.39.2.49 ginsidefirst

```
int M_const::ginsidefirst
```

Definition at line 1372 of file structs.h.

3.39.2.50 gDefDim

```
int M_const::gDefDim
```

Definition at line 1373 of file structs.h.

3.39.2.51 gDefDim4

```
int M_const::gDefDim4
```

Definition at line 1374 of file structs.h.

3.39.2.52 NumFixedSets

```
int M_const::NumFixedSets
```

Definition at line 1375 of file structs.h.

3.39.2.53 NumFixedFunctions

```
int M_const::NumFixedFunctions
```

Definition at line 1376 of file structs.h.

3.39.2.54 rbufnum

```
int M_const::rbufnum
```

Definition at line 1377 of file structs.h.

3.39.2.55 dbufnum

```
int M_const::dbufnum
```

Definition at line 1378 of file structs.h.

3.39.2.56 sbufnum

```
int M_const::sbufnum
```

Definition at line 1379 of file structs.h.

3.39.2.57 zbufnum

```
int M_const::zbufnum
```

Definition at line 1380 of file structs.h.

3.39.2.58 SkipClears

```
int M_const::SkipClears
```

Definition at line 1381 of file structs.h.

3.39.2.59 gTokensWriteFlag

```
int M_const::gTokensWriteFlag
```

Definition at line 1382 of file structs.h.

3.39.2.60 gfunpowers

```
int M_const::gfunpowers
```

Definition at line 1383 of file structs.h.

3.39.2.61 gStatsFlag

```
int M_const::gStatsFlag
```

3.44.1 Detailed Description

The N_const struct is part of the global data and resides either in the ALLGLOBALS struct A, or the ALLPRIVATES struct B (TFORM) under the name N We see it used with the macro AN as in AN.RepFunNum It has variables that are private to each thread and are used as temporary storage during the expansion of the terms tree.

```
char nameblock::names[NAMETABLESIZE]
```

Definition at line 117 of file minos.h.

The documentation for this struct was generated from the following file:

- minos.h

3.46 NaMeNode Struct Reference

```
#include <structs.h>
```

Data Fields

- LONG name
- WORD parent
- WORD left
- WORD right
- WORD balance
- WORD type
- WORD number

3.46.1 Detailed Description

The names of variables are kept in an array. Elements of type NAMENODE define a tree (that is kept balanced) that make it easy and fast to look for variables. See also NAMETREE.

Definition at line 234 of file structs.h.

3.46.2 Field Documentation

3.46.2.1 name

```
LONG NaMeNode::name
```

Offset into NAMETREE::namebuffer.

Definition at line 235 of file structs.h.

3.46.2.2 parent

```
WORD NaMeNode::parent
```

=-1 if no parent.

Definition at line 236 of file structs.h.

3.46.2.3 left

```
WORD NaMeNode::left
```

=-1 if no child.

Definition at line 237 of file structs.h.

3.46.2.4 right

```
WORD NaMeNode::right
```

=-1 if no child.

Definition at line 238 of file structs.h.

3.46.2.5 balance

```
WORD NaMeNode::balance
```

Used for the balancing of the tree.

Definition at line 239 of file structs.h.

3.46.2.6 type

```
WORD NaMeNode::type
```

Type associated with the name. See compiler types.

Definition at line 240 of file structs.h.

3.46.2.7 number

```
WORD NaMeNode::number
```

Number of variable in LIST's like for example C_const::SymbolList.

Definition at line 241 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.47 NaMeTree Struct Reference

- UBYTE * namebuffer
- LONG nodesize
- LONG nodefill
- LONG namesize
- LONG namefill
- LONG oldnamefill
- LONG oldnodefill
- LONG globalnamefill
- LONG globalnodefill
- LONG clearnamefill
- LONG clearnodefill
- WORD headnode

3.47.1 Detailed Description

A struct of type NAMETREE controls a complete (balanced) tree of names for the compiler. The compiler maintains several of such trees and the system has been set up in such a way that one could define more of them if we ever want to work with local name spaces.

Definition at line 252 of file structs.h.

3.47.2 Field Documentation

3.47.2.1 namenode

```
NAMENODE* NaMeTree::namenode
```

[D] Vector of NAMENODE's. Number of elements is nodesize. =0 if no memory has been allocated.

Definition at line 253 of file structs.h.

3.47.2.2 namebuffer

```
UBYTE* NaMeTree::namebuffer
```

[D] Buffer that holds all the name strings refered to by the NAMENODE's. Allocation size is namesize. =0 if no memory has been allocated.

Definition at line 255 of file structs.h.

3.47.2.3 nodesize

```
LONG NaMeTree::nodesize
```

Maximum number of elements in namenode.

Definition at line 258 of file structs.h.

3.47.2.4 nodefill

```
LONG NaMeTree::nodefill
```

Number of currently used nodes in namenode.

Definition at line 259 of file structs.h.

3.47.2.5 namesize

```
LONG NaMeTree::namesize
```

Allocation size of namebuffer in bytes.

Definition at line 260 of file structs.h.

3.47.2.6 namefill

```
LONG NaMeTree::namefill
```

Number of bytes occupied.

Definition at line 261 of file structs.h.

3.47.2.7 oldnamefill

```
LONG NaMeTree::oldnamefill
```

UNUSED

Definition at line 262 of file structs.h.

3.47.2.8 oldnodefill

```
LONG NaMeTree::oldnodefill
```

UNUSED

Definition at line 263 of file structs.h.

3.47.2.9 globalnamefill

```
LONG NaMeTree::globalnamefill
```

Set by .global statement to the value of namefill. When a .store command is processed, this value will be used to reset namefill.

Definition at line 264 of file structs.h.

3.47.2.10 globalnodefill

```
LONG NaMeTree::globalnodefill
```

Same usage as globalnamefill, but for nodefill.

Definition at line 266 of file structs.h.

3.47.2.11 clearnamefill

```
LONG NaMeTree::clearnamefill
```

Marks the reset point used by the .clear statement.

Definition at line 267 of file structs.h.

3.47.2.12 clearnodefill

```
LONG NaMeTree::clearnodefill
```

Marks the reset point used by the .clear statement.

Definition at line 268 of file structs.h.

3.47.2.13 headnode

```
WORD NaMeTree::headnode
```

Offset in namenode of head node. =-1 if tree is empty.

Definition at line 269 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.48 NeStInG Struct Reference

```
#include <structs.h>
```

Data Fields

- WORD * termsize
- WORD * funsize
- WORD * argsize

3.48.1 Detailed Description

The NESTING struct is used when we enter the argument of functions and there is the possibility that we have to change something there. Because functions can be nested we have to keep track of all levels of functions in case we have to move the outer layers to make room for a larger function argument.

Definition at line 982 of file structs.h.

3.48.2 Field Documentation

3.48.2.1 termsize

```
WORD* NeStInG::termsize
```

Definition at line 983 of file structs.h.

3.48.2.2 funsize

```
WORD* NeStInG::funsize
```

Definition at line 984 of file structs.h.

3.48.2.3 argsize

```
WORD* NeStInG::argsize
```

Definition at line 985 of file structs.h.

3.54.1 Detailed Description

The P_const struct is part of the global data and resides in the ALLGLOBALS struct A under the name P We see it used with the macro AP as in AP.InOutBuf It contains objects that have dealings with the preprocessor.

Definition at line 1500 of file structs.h.

3.66.1 Detailed Description

The R_const struct is part of the global data and resides either in the ALLGLOBALS struct A, or the ALLPRIVATES struct B (TFORM) under the name R We see it used with the macro AR as in AR.infile It has the variables that define the running environment and that should be transferred with a term in a multithreaded run.

The documentation for this struct was generated from the following file:

- structs.h

3.70 SETUPPARAMETERS Struct Reference

```
#include <structs.h>
```

Data Fields

- UBYTE * parameter
- int type
- int flags
- LONG value

3.70.1 Detailed Description

Each setup parameter has one element of the struct SETUPPARAMETERS assigned to it. By binary search in the array of them we can then locate the proper element by name. We have to assume that two ints make a long and either one or two longs make a pointer. The long before the ints and padding gives a problem in the initialization.

Definition at line 967 of file structs.h.

3.72.1 Detailed Description

The struct SORTING is used to control a sort operation. It includes a small and a large buffer and arrays for keeping track of various stages of the (merge) sorts. Each sort level has its own struct and different levels can have different sizes for its arrays. Also different threads have their own set of SORTING structs.

- UBYTE sFun
- UBYTE maxpower [16]
- UBYTE wildoffset [16]
- UBYTE revision
- UBYTE reserved [512-8-4-16-4-16-16-1]

3.75.1 Detailed Description

Defines the structure of the file header for store-files and save-files.

The first 8 bytes serve as a unique mark to identity save-files that contain such a header. Older versions of FORM don't have this header and will write the POSITION of the next file index (struct FiLeInDeX) here, which is always different from this pattern.

It is always 512 bytes long.

Definition at line 74 of file structs.h.

3.75.2 Field Documentation

3.75.2.1 headermark

```
UBYTE STOREHEADER::headermark[8]
```

Pattern for header identification. Old versions of FORM have a maximum sizeof(POSITION) of 8

Definition at line 75 of file structs.h.

3.75.2.2 lenWORD

```
UBYTE STOREHEADER::lenWORD
```

Number of bytes for WORD

Definition at line 77 of file structs.h.

3.76.1 Detailed Description

Input is read from 'streams' which are represented by objects of type STREAM. A stream can be a file, a do-loop, a procedure, the string value of a preprocessor variable ..... When a new stream is opened we have to keep information about where to fall back in the parent stream to allow this to happen even in the middle of reading names etc as would be the case with a`i'b

Definition at line 674 of file structs.h.

3.79.1 Detailed Description

The T_const struct is part of the global data and resides either in the ALLGLOBALS struct A, or the ALLPRIVATES struct B (TFORM) under the name T We see it used with the macro AT as in AT.WorkPointer It has variables that are private to each thread, most of which have to be defined at startup.

3.82.1 Detailed Description

buffers, mm, flags, and prototype are always dynamically allocated, tablepointers only if needed (=0 if unallocated), boomlijst and argtail only for sparse tables.

Allocation is done for both the normal and the stub instance (spare), except for prototype and argtail which share memory.

Definition at line 337 of file structs.h.

3.82.2 Field Documentation

3.82.2.1 tablepointers

```
WORD* TaBlEs::tablepointers
```

[D] Start in tablepointers table.

Definition at line 338 of file structs.h.

3.82.2.2 prototype

```
WORD* TaBlEs::prototype
```

[D] The wildcard prototyping for arguments

Definition at line 343 of file structs.h.

Referenced by DoRecovery(), and TestSub().

3.82.2.3 pattern

```
WORD* TaBlEs::pattern
```

The pattern with which to match the arguments

Definition at line 344 of file structs.h.

Referenced by DoRecovery(), and TestSub().

3.82.2.4 mm

```
MINMAX* TaBlEs::mm
```

[D] Array bounds, dimension by dimension. # elements = numind.

Definition at line 346 of file structs.h.

Referenced by DoRecovery(), and TestSub().

3.82.2.5 flags

```
WORD* TaBlEs::flags
```

[D] Is element in use ? etc. # elements = numind.

Definition at line 347 of file structs.h.

Referenced by DoRecovery().

3.82.2.6 boomlijst

```
COMPTREE* TaBlEs::boomlijst
```

[D] Tree for searching in sparse tables

Definition at line 348 of file structs.h.

Referenced by DoRecovery().

3.82.2.7 argtail

```
UBYTE* TaBlEs::argtail
```

[D] The arguments in characters. Starts for tablebase with parenthesis to indicate tail

Definition at line 349 of file structs.h.

Referenced by DoRecovery().

3.82.2.8 spare

```
struct TaBlEs* TaBlEs::spare
```

[D] For tablebase. Alternatingly stubs and real

Definition at line 351 of file structs.h.

Referenced by DoRecovery().

3.82.2.9 buffers

```
WORD* TaBlEs::buffers
```

[D] When we use more than one compiler buffer.

Definition at line 352 of file structs.h.

Referenced by AddRHS(), and DoRecovery().

3.82.2.10 totind

```
LONG TaBlEs::totind
```

Total number requested

Definition at line 353 of file structs.h.

Referenced by DoRecovery().

3.82.2.11 reserved

```
LONG TaBlEs::reserved
```

Total reservation in tablepointers for sparse

Definition at line 354 of file structs.h.

Referenced by DoRecovery().

3.82.2.12 defined

```
LONG TaBlEs::defined
```

Number of table elements that are defined

Definition at line 355 of file structs.h.

3.82.2.13 mdefined

```
LONG TaBlEs::mdefined
```

Same as defined but after .global

Definition at line 356 of file structs.h.

3.82.2.14 prototypeSize

```
int TaBlEs::prototypeSize
```

Size of allocated memory for prototype in bytes.

Definition at line 357 of file structs.h.

Referenced by DoRecovery().

3.82.2.15 numind

```
int TaBlEs::numind
```

Number of array indices

Definition at line 358 of file structs.h.

Referenced by DoRecovery(), and TestSub().

3.82.2.16 bounds

```
int TaBlEs::bounds
```

Array bounds check on/off.

Definition at line 359 of file structs.h.

Referenced by TestSub().

3.82.2.17 strict

```
int TaBlEs::strict
```

>0: all must be defined. <0: undefined not substitute

Definition at line 360 of file structs.h.

3.84.1 Detailed Description

The struct TRACES keeps track of the progress during the expansion of a 4-dimensional trace. Each time a term gets generated the expansion tree continues in the next statement. When it returns it has to know where to continue. The 4-dimensional traces are more complicated than the n-dimensional traces (see TRACEN) because of the extra tricks that can be used. They are responsible for the shorter final expressions.

Definition at line 727 of file structs.h.

The documentation for this struct was generated from the following file:

- structs.h

3.85 tree Struct Reference

```
#include <structs.h>
```

Data Fields

- int parent
- int left
- int right
- int value
- int blnce
- int usage

3.85.1 Detailed Description

The subexpressions in the compiler are kept track of in a (balanced) tree to reduce the need for subexpressions and hence save much space in large rhs expressions (like when we have xxxxxxx occurrences of objects like f(x+1,x+1) in which each x+1 becomes a subexpression. The struct that controls this tree is COMPTREE.

Definition at line 281 of file structs.h.

3.85.2 Field Documentation

3.85.2.1 parent

```
int tree::parent
```

Index of parent

Definition at line 282 of file structs.h.

Referenced by IniFbuffer().

3.85.2.2 left

```
int tree::left
```

Left child (if not -1)

Definition at line 283 of file structs.h.

Referenced by IniFbuffer().

4.1.1 Detailed Description

Contains the routines that deal with the execution phase of the argument and related statements (like term)

Definition in file argument.c.

4.1.2 Macro Definition Documentation

4.1.2.1 NEWORDER

```
#define NEWORDER
```

Factorizes an argument in general notation (meaning that the first word of the argument is a positive size indicator) Input (argin): pointer to the complete argument Output (argout): Pointer to where the output should be written. This is in the WorkSpace Return value should be negative if anything goes wrong.

The notation of the output should be a string of arguments terminated by the number zero.

Originally we sorted in a way that the constants came last. This gave conflicts with the dollar and expression factorizations (in the expressions we wanted the zero first and then followed by the constants).

Definition at line 2013 of file argument.c.

4.1.3 Function Documentation

4.1.3.1 execarg()

```
WORD execarg (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 56 of file argument.c.

4.1.3.2 execterm()

```
WORD execterm (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 1724 of file argument.c.

4.1.3.3 ArgumentImplode()

```
int ArgumentImplode (
            PHEAD WORD * term,
            WORD * thelist )
```

Definition at line 1800 of file argument.c.

4.1.3.4 ArgumentExplode()

```
int ArgumentExplode (
            PHEAD WORD * term,
            WORD * thelist )
```

Definition at line 1904 of file argument.c.

4.1.3.5 ArgFactorize()

```
int ArgFactorize (
            PHEAD WORD * argin,
            WORD * argout )
```

Definition at line 2015 of file argument.c.

4.1.3.6 FindArg()

```
WORD FindArg (
            PHEAD WORD * a )
```

Looks the argument up in the (workers) table. If it is found the number in the table is returned (plus one to make it positive). If it is not found we look in the compiler provided table. If it is found - the number in the table is returned (minus one to make it negative). If in neither table we return zero.

Definition at line 2463 of file argument.c.

4.1.3.7 InsertArg()

```
WORD InsertArg (
            PHEAD WORD * argin,
            WORD * argout,
            int par )
```

Inserts the argument into the (workers) table. If the table is too full we eliminate half of it. The eliminated elements are the ones that have not been used most recently, weighted by their total use and age(?). If par == 0 it inserts in the regular factorization cache If par == 1 it inserts in the cache defined with the FactorCache statement

Definition at line 2487 of file argument.c.

References AddNtoC(), AddRHS(), and CleanupArgCache().

Here is the call graph for this function:

4.1.3.8 CleanupArgCache()

```
int CleanupArgCache (
            PHEAD WORD bufnum )
```

Cleans up the argument factorization cache. We throw half the elements. For a weight of what we want to keep we use the product of usage and the number in the buffer.

Definition at line 2522 of file argument.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::Pointer, CbUf::rhs, SortWeights(), and tree::usage.

Referenced by InsertArg().

Here is the call graph for this function:

4.1.3.9 ArgSymbolMerge()

```
int ArgSymbolMerge (
            WORD * t1,
            WORD * t2 )
```

Definition at line 2593 of file argument.c.

4.1.3.10 ArgDotproductMerge()

```
int ArgDotproductMerge (
            WORD * t1,
            WORD * t2 )
```

Definition at line 2648 of file argument.c.

4.1.3.11 TakeArgContent()

```
WORD * TakeArgContent (
            PHEAD WORD * argin,
            WORD * argout )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. The common pieces are put in argout as a sequence of arguments. The part with the multiple terms that are now relative prime is put in argfree which is allocated via TermMalloc and is given as the return value. The difference with the old code is that negative powers are always removed. Hence it is as in MakeInteger in which only numerators will be left: now only zero or positive powers will be remaining.

Definition at line 2716 of file argument.c.

References EndSort(), MakeInteger(), MakeMod(), NewSort(), and StoreTerm().

Here is the call graph for this function:

4.1.3.12 MakeInteger()

```
WORD * MakeInteger (
            PHEAD WORD * argin,
            WORD * argout,
            WORD * argfree )
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in argin. The number that comes out should go to argout. The new pointer in the argout buffer is the return value. The normalized argument is in argfree.

Definition at line 3262 of file argument.c.

Referenced by TakeArgContent().

4.1.3.13 MakeMod()

```
WORD * MakeMod (
            PHEAD WORD * argin,
            WORD * argout,
            WORD * argfree )
```

Similar to MakeInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3433 of file argument.c.

References GetModInverses().

Referenced by TakeArgContent().

Here is the call graph for this function:

4.1.3.14 SortWeights()

```
void SortWeights (
            LONG * weights,
            LONG * extraspace,
            WORD number )
```

Sorts an array of LONGS in the same way SplitMerge (in sort.c) works We use gradual division in two.

Definition at line 3478 of file argument.c.

References SortWeights().

Referenced by CleanupArgCache(), and SortWeights().

Here is the call graph for this function:

4.5.1 Detailed Description

Contains all functions that deal with the recovery mechanism controlled and activated by the On Checkpoint switch.

The main function are DoCheckpoint, DoRecovery, and DoSnapshot. If the checkpoints are activated DoCheckpoint is called every time a module is finished executing. If the conditions for the creation of a recovery snapshot are met DoCheckpoint calls DoSnapshot. DoRecovery is called once when FORM starts up with the command line argument -R. Most of the other code contains debugging facilities that are only compiled if the macro PRINTDEBUG is defined.

The recovery mechanism is atomic, i.e. only if everything went well, the final recovery file is created (and the older one overwritten) in a single step (copying). If some errors occur, a warning is issued and the program continues without having created a new recovery file. The only situation in which the creation of the recovery data leads to a termination of the running program is if not enough disk or memory space is left.

For ParFORM each slave creates its own recovery file, sends it to the master and then it deletes the recovery file. The master stores all the recovery files and on recovery it feeds these files to the slaves. It is nearly impossible to recover after some MPI fault so ParFORM terminates on any recovery failure.

DoRecovery and DoSnapshot do the loading and saving of the recovery data, respectively. Every change in one functions needs to be accompanied by the appropriate change in the other function. The structure of both functions is quite similar. They handle the relevant global structs one after the other and then care about the copying of the hide and scratch files.

The names of the recovery, scratch and hide files are hard-coded in the variables in fold "filenames and system commands".

If the global structs AM,AP,AC,AR are changed, DoRecovery and DoSnapshot usually also have to be changed. Some structs are read/written as a whole (AP,AC), some are read/written only partly as a selection of their individual elements (AM,AR). If AM or AR have been changed by adding or removing an element that is important for the runtime status, then the reading/writing statements have to be added to or removed from DoRecovery and Do↩Snapshot. If AP or AC are changed, then for non-pointer variables (in the case of a struct it also means that none of its elements is a pointer) nothing has to be changed in the functions here. If pointers are involved, extra code has to be added (or removed). See the comments of DoRecovery and DoSnapshot.

4.5.2.17 ANNOUNCE

```
#define ANNOUNCE(
            str )
```

Definition at line 1367 of file checkpoint.c.

4.5.3 Function Documentation

4.5.3.1 CheckRecoveryFile()

```
int CheckRecoveryFile ( )
```

Checks whether a snapshot/recovery file exists. Returns 1 if it exists, 0 otherwise.

Definition at line 278 of file checkpoint.c.

References RecoveryFilename().

Here is the call graph for this function:

4.5.3.2 DeleteRecoveryFile()

```
void DeleteRecoveryFile ( )
```

Deletes the recovery files. It is called by CleanUp() in the case of a successful completion.

Definition at line 333 of file checkpoint.c.

4.5.3.3 RecoveryFilename()

```
char * RecoveryFilename ( )
```

Returns pointer to recovery filename.

Definition at line 364 of file checkpoint.c.

Referenced by CheckRecoveryFile(), and DoRecovery().

4.5.3.4 InitRecovery()

```
void InitRecovery ( )
```

Sets up the strings for the filenames of the recovery files. This functions should only be called once to avoid memory leaks and after AM.TempDir has been initialized.

Definition at line 399 of file checkpoint.c.

4.5.3.5 fwrite_cached()

```
size_t fwrite_cached (
            const void * ptr,
            size_t size,
            size_t nmemb,
            FILE * fd )
```

Definition at line 1219 of file checkpoint.c.

4.5.3.6 flush_cache()

```
size_t flush_cache (
            FILE * fd )
```

Definition at line 1244 of file checkpoint.c.

4.5.3.7 DoRecovery()

```
int DoRecovery (
            int * moduletype )
```

Reads from the recovery file and restores all necessary variables and states in FORM, so that the execution can recommence in preprocessor() as if no restart of FORM had occurred.

The recovery file is read into memory as a whole. The pointer p then points into this memory at the next non-processed data. The macros by which variables are restored, like R_SET, automatically increase p appropriately.

If something goes wrong, the function returns with a non-zero value.

Allocated memory that would be lost when overwriting the global structs with data from the file is freed first. A major part of the code deals with the restoration of pointers. The idiom we use is to memorize the original pointer value (org), allocate new memory and copy the data from the file into this memory, calculate the offset between the old pointer value and the new allocated memory position (ofs), and then correct all affected pointers (+=ofs).

We rely on the fact that several variables (especially in AM) are already assigned the correct values by the startup functions. That means, in principle, that a change in the setup files between snapshot creation and recovery will be noticed.

Definition at line 1399 of file checkpoint.c.

Here is the call graph for this function:

4.5.3.8 DoCheckpoint()

```
void DoCheckpoint (
            int moduletype )
```

Checks whether a snapshot should be done. Calls DoSnapshot() to create the snapshot.

Definition at line 3102 of file checkpoint.c.

References PF_BroadcastNumber(), PF_RecvFile(), PF_SendFile(), and TimeWallClock().

Here is the call graph for this function:

4.5.4 Variable Documentation

4.5.4.1 cache_buffer

```
unsigned char cache_buffer[CACHE_SIZE]
```

Definition at line 1216 of file checkpoint.c.

4.5.4.2 cache_fill

```
size_t cache_fill = 0
```

Definition at line 1217 of file checkpoint.c.

4.7.1 Detailed Description

Compiler routines for statements that involve algebraic expressions. These involve definitions, id-statements, the multiply statement and the fill statement.

Definition in file comexpr.c.

4.7.2 Function Documentation

4.7.2.1 CoLocal()

```
int CoLocal (
            UBYTE * inp )
```

Definition at line 66 of file comexpr.c.

4.7.2.2 CoGlobal()

```
int CoGlobal (
            UBYTE * inp )
```

Definition at line 73 of file comexpr.c.

4.7.2.3 CoLocalFactorized()

```
int CoLocalFactorized (
            UBYTE * inp )
```

Definition at line 80 of file comexpr.c.

4.7.2.4 CoGlobalFactorized()

```
int CoGlobalFactorized (
            UBYTE * inp )
```

Definition at line 87 of file comexpr.c.

4.7.2.5 DoExpr()

```
int DoExpr (
            UBYTE * inp,
            int type,
            int par )
```

Definition at line 96 of file comexpr.c.

4.7.2.6 CoIdOld()

```
int CoIdOld (
            UBYTE * inp )
```

Definition at line 380 of file comexpr.c.

4.7.2.7 CoId()

```
int CoId (
            UBYTE * inp )
```

Definition at line 391 of file comexpr.c.

4.7.2.8 CoIdNew()

```
int CoIdNew (
            UBYTE * inp )
```

Definition at line 402 of file comexpr.c.

4.7.2.9 CoDisorder()

```
int CoDisorder (
            UBYTE * inp )
```

Definition at line 413 of file comexpr.c.

4.7.2.10 CoMany()

```
int CoMany (
            UBYTE * inp )
```

Definition at line 424 of file comexpr.c.

4.7.2.11 CoMulti()

```
int CoMulti (
            UBYTE * inp )
```

Definition at line 435 of file comexpr.c.

4.7.2.12 CoIfMatch()

```
int CoIfMatch (
            UBYTE * inp )
```

Definition at line 446 of file comexpr.c.

4.7.2.13 CoIfNoMatch()

```
int CoIfNoMatch (
            UBYTE * inp )
```

Definition at line 457 of file comexpr.c.

4.7.2.14 CoOnce()

```
int CoOnce (
            UBYTE * inp )
```

Definition at line 468 of file comexpr.c.

4.7.2.15 CoOnly()

```
int CoOnly (
            UBYTE * inp )
```

Definition at line 479 of file comexpr.c.

4.7.2.16 CoSelect()

```
int CoSelect (
            UBYTE * inp )
```

Definition at line 490 of file comexpr.c.

4.7.2.17 CoIdExpression()

```
int CoIdExpression (
            UBYTE * inp,
            int type )
```

Definition at line 503 of file comexpr.c.

4.7.2.18 CoMultiply()

```
int CoMultiply (
            UBYTE * inp )
```

Definition at line 1024 of file comexpr.c.

4.7.2.19 CoFill()

```
int CoFill (
            UBYTE * inp )
```

Definition at line 1063 of file comexpr.c.

4.7.2.20 CoFillExpression()

```
int CoFillExpression (
            UBYTE * inp )
```

Definition at line 1339 of file comexpr.c.

4.7.2.21 CoPrintTable()

```
int CoPrintTable (
            UBYTE * inp )
```

Definition at line 1725 of file comexpr.c.

4.7.2.22 CoAssign()

```
int CoAssign (
            UBYTE * inp )
```

Definition at line 1901 of file comexpr.c.

4.7.2.23 CoDeallocateTable()

```
int CoDeallocateTable (
            UBYTE * inp )
```

Definition at line 1959 of file comexpr.c.

4.9.1 Detailed Description

Compiler routines for most statements that don't involve algebraic expressions. Exceptions: all routines involving declarations are in the file names.c When making new statements one can add the compiler routines here and have a look whether there is already a routine that is similar. In that case one can make a copy and modify it.

4.9.2 Function Documentation

4.9.2.1 CoCollect()

```
int CoCollect (
            UBYTE * s )
```

Definition at line 143 of file compcomm.c.

4.9.2.2 setonoff()

```
int setonoff (
            UBYTE * s,
            int * flag,
            int onvalue,
            int offvalue )
```

Definition at line 205 of file compcomm.c.

4.9.2.3 CoCompress()

```
int CoCompress (
            UBYTE * s )
```

Definition at line 221 of file compcomm.c.

4.9.2.4 CoFlags()

```
int CoFlags (
            UBYTE * s,
            int value )
```

Definition at line 270 of file compcomm.c.

4.9.2.5 CoOff()

```
int CoOff (
            UBYTE * s )
```

Definition at line 305 of file compcomm.c.

4.9.2.6 CoOn()

```
int CoOn (
            UBYTE * s )
```

Definition at line 362 of file compcomm.c.

4.9.2.7 CoInsideFirst()

```
int CoInsideFirst (
            UBYTE * s )
```

Definition at line 609 of file compcomm.c.

4.9.2.8 CoProperCount()

```
int CoProperCount (
            UBYTE * s )
```

Definition at line 616 of file compcomm.c.

4.9.2.9 CoDelete()

```
int CoDelete (
            UBYTE * s )
```

Definition at line 623 of file compcomm.c.

4.9.2.10 CoFormat()

```
int CoFormat (
            UBYTE * s )
```

Definition at line 668 of file compcomm.c.

4.9.2.11 CoKeep()

```
int CoKeep (
            UBYTE * s )
```

Definition at line 900 of file compcomm.c.

4.9.2.12 CoFixIndex()

```
int CoFixIndex (
            UBYTE * s )
```

Definition at line 912 of file compcomm.c.

4.9.2.13 CoMetric()

```
int CoMetric (
            UBYTE * s )
```

Definition at line 946 of file compcomm.c.

4.9.2.14 DoPrint()

```
int DoPrint (
            UBYTE * s,
            int par )
```

Definition at line 954 of file compcomm.c.

4.9.2.15 CoPrint()

```
int CoPrint (
            UBYTE * s )
```

Definition at line 1142 of file compcomm.c.

4.9.2.16 CoPrintB()

```
int CoPrintB (
            UBYTE * s )
```

Definition at line 1149 of file compcomm.c.

4.9.2.17 CoNPrint()

```
int CoNPrint (
            UBYTE * s )
```

Definition at line 1156 of file compcomm.c.

4.9.2.18 CoPushHide()

```
int CoPushHide (
            UBYTE * s )
```

Definition at line 1163 of file compcomm.c.

4.9.2.19 CoPopHide()

```
int CoPopHide (
            UBYTE * s )
```

Definition at line 1207 of file compcomm.c.

4.9.2.20 SetExprCases()

```
int SetExprCases (
            int par,
            int setunset,
            int val )
```

Definition at line 1242 of file compcomm.c.

4.9.2.21 SetExpr()

```
int SetExpr (
            UBYTE * s,
            int setunset,
            int par )
```

Definition at line 1388 of file compcomm.c.

4.9.2.22 CoDrop()

```
int CoDrop (
            UBYTE * s )
```

Definition at line 1433 of file compcomm.c.

4.9.2.23 CoNoDrop()

```
int CoNoDrop (
            UBYTE * s )
```

Definition at line 1440 of file compcomm.c.

4.9.2.24 CoSkip()

```
int CoSkip (
            UBYTE * s )
```

Definition at line 1447 of file compcomm.c.

4.9.2.25 CoNoSkip()

```
int CoNoSkip (
            UBYTE * s )
```

Definition at line 1454 of file compcomm.c.

4.9.2.26 CoHide()

```
int CoHide (
            UBYTE * inp )
```

Definition at line 1461 of file compcomm.c.

4.9.2.27 CoIntoHide()

```
int CoIntoHide (
            UBYTE * inp )
```

Definition at line 1479 of file compcomm.c.

4.9.2.28 CoNoHide()

```
int CoNoHide (
            UBYTE * inp )
```

Definition at line 1497 of file compcomm.c.

4.9.2.29 CoUnHide()

```
int CoUnHide (
            UBYTE * inp )
```

Definition at line 1504 of file compcomm.c.

4.9.2.30 CoNoUnHide()

```
int CoNoUnHide (
            UBYTE * inp )
```

Definition at line 1511 of file compcomm.c.

4.9.2.31 AddToCom()

```
void AddToCom (
            int n,
            WORD * array )
```

Definition at line 1518 of file compcomm.c.

4.9.2.32 AddComString()

```
int AddComString (

/*
    #] CoMultiBracket :
    #[ CountComp :

        This routine reads the count statement. The syntax is:
        count minimum,object,size[,object,size]
        Objects can be:
            symbol
            dotproduct
            vector
            function
        Vectors can have the auxiliary flags:
            +v +f +d +?setname

        Output for the compiler:
        TYPECOUNT,size,minimum,objects
        with the objects:
        SYMBOL,4,number,size
        DOTPRODUCT,5,v1,v2,size
        FUNCTION,4,number,size
        VECTOR,5,number,bits,size or VECTOR,6,number,bits,setnumber,size

        Currently only used in the if statement

4.11.1 Detailed Description

The heart of the compiler. It contains the tables of statements. It finds the statements in the tables and calls the proper routines. For algebraic expressions it runs the compilation by first calling the tokenizer, splitting things into subexpressions and generating the code. There is a system for recognizing already existing subexpressions. This economizes on the length of the output.

Note: the compiler of FORM doesn't attempt to normalize the input. Hence x+1 and 1+x are different objects during compilation. Similarly (a+b-b) will not be simplified to (a).

        #] CompileSubExpressions :
        #[ CodeGenerator :

        This routine does the real code generation.
        It returns the number of the rhs subexpression.
        At this point we do not have to worry about subexpressions,
        sets, setelements, simple vs complicated function arguments
        simple vs complicated powers etc.

        The variable 'first' indicates whether we are starting a new term

        The major complication are the set elements of type set[n].
        We have marked them as TSETNUM,n,Ttype,setnum
        They go into
        SETSET,size,subterm,relocation list
        in which the subterm should be ready to become a regular
        subterm in which the sets have been replaced by their element
        The relocation list consists of pairs of numbers:
        1: offset in the subterm, 2: the symbol n.
        Note that such a subterm can be a whole function with its arguments.
        We use the variable inset to indicate that we have something going.
        The relocation list is collected in the top of the WorkSpace.

/*
        #] CompleteTerm :
        #[ CodeFactors :

        This routine does the part of reading in in terms of factors.
        If there is more than one term at this level we have only one
        factor. In that case any expression should first be unfactorized.
        Then the whole expression gets read as a new subexpression and finally
        we generate factor_*subexpression.
        If the whole has only multiplications we have factors. Then the
        nasty thing is powers of objects and in particular powers of
        factorized expressions or dollars.
        For a power we generate a new subexpression of the type
          1+factor_+...+factor_^(power-1)
        with which we multiply.

        WE HAVE NOT YET WORRIED ABOUT SETS

#ifdef WITHZLIB
/*
#define GZIPDEBUG

    Low level routines for dealing with zlib during sorting and handling
    the scratch files. Work started 5-sep-2005.
    The .sor file handling was more or less completed on 8-sep-2005
    The handling of the scratch files still needs some thinking.
    Complications are:
        gzip compression should be per expression, not per buffer.
        No gzip compression for expressions with a bracket index.
        Separate decompression buffers for expressions in the rhs.
        This last one will involve more buffer work and organization.
        Information about compression should be stored for each expr.
            (including what method/program was used)
    Note: Be careful with compression. By far the most compact method
    is the original problem....

    #[ Variables :

    The following variables are to contain the intermediate buffers
    for the inflation of the various patches in the sort file.
    There can be up to MaxFpatches (FilePatches in the setup) and hence
    we can have that many streams simultaneously. We set this up once
    and only when needed.
        (in struct A.N or AB[threadnum].N)
    Bytef **AN.ziobufnum;
    Bytef *AN.ziobuffers;

4.15.1 Detailed Description

Utility routines for the compiler.

Definition in file comtool.c.

4.15.2 Function Documentation

4.15.2.1 inicbufs()

```
int inicbufs (
            VOID  )
```

Creates a new compiler buffer and returns its ID number.

Returns

The ID number for the new compiler buffer.

Definition at line 47 of file comtool.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::BufferSize, CbUf::CanCommu, CbUf::dimension, CbUf::lhs, CbUf::numdum, CbUf::NumTerms, CbUf::Pointer, CbUf::rhs, and CbUf::Top.

Referenced by AddRHS(), and StartVariables().

4.15.2.2 finishcbuf()

```
void finishcbuf (
            WORD num )
```

Frees a compiler buffer.

Parameters

num	The ID number for the buffer to be freed.

Definition at line 89 of file comtool.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::BufferSize, CbUf::CanCommu, CbUf::lhs, CbUf::NumTerms, CbUf::Pointer, CbUf::rhs, and CbUf::Top.

Referenced by PF_BroadcastCBuf().

4.15.2.3 clearcbuf()

```
void clearcbuf (
            WORD num )
```

Clears contents in a compiler buffer.

Parameters

num	The ID number for the buffer to be cleared.

Definition at line 116 of file comtool.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::Pointer, and CbUf::rhs.

4.15.2.4 DoubleCbuffer()

```
WORD * DoubleCbuffer (
            int num,
            WORD * w,
            int par )
```

Doubles a compiler buffer.

Parameters

num	The ID number for the buffer to be doubled.
w	The pointer to the end (exclusive) of the current buffer. The contents in the range of [cbuf[num].Buffer,w) will be kept.

Definition at line 143 of file comtool.c.

References CbUf::Buffer, CbUf::BufferSize, CbUf::lhs, CbUf::Pointer, CbUf::rhs, and CbUf::Top.

Referenced by AddNtoC(), AddNtoL(), and TestSub().

4.15.2.5 AddLHS()

```
WORD * AddLHS (
            int num )
```

Adds an LHS to a compiler buffer and returns the pointer to a buffer for the new LHS.

Parameters

num	The ID number for the buffer to get another LHS.

Definition at line 188 of file comtool.c.

References CbUf::lhs, and CbUf::Pointer.

Referenced by AddNtoL().

4.15.2.6 AddRHS()

```
WORD * AddRHS (
            int num,
            int type )
```

Adds an RHS to a compiler buffer and returns the pointer to a buffer for the new RHS.

Parameters

num	The ID number for the buffer to get another RHS.
type	If 0, the subexpression tree will be reallocated.

Definition at line 214 of file comtool.c.

References TaBlEs::buffers, TaBlEs::buffersfill, TaBlEs::bufferssize, TaBlEs::bufnum, CbUf::CanCommu, CbUf::dimension, inicbufs(), CbUf::numdum, CbUf::NumTerms, CbUf::Pointer, and CbUf::rhs.

Referenced by InsertArg(), StartVariables(), TestMatch(), and TestSub().

Here is the call graph for this function:

4.15.2.7 AddNtoL()

```
int AddNtoL (
            int n,
            WORD * array )
```

Adds an LHS with the given data to the current compiler buffer.

Parameters

n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 288 of file comtool.c.

References AddLHS(), DoubleCbuffer(), CbUf::Pointer, and CbUf::Top.

Here is the call graph for this function:

4.15.2.8 AddNtoC()

```
int AddNtoC (
            int bufnum,
            int n,
            WORD * array,
            int par )
```

Adds the given data to the last LHS/RHS in a compiler buffer.

Parameters

bufnum	The ID number for the buffer where the data will be added.
n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 317 of file comtool.c.

References DoubleCbuffer(), CbUf::Pointer, and CbUf::Top.

Referenced by InsertArg(), and StartVariables().

Here is the call graph for this function:

4.15.2.9 InsTree()

```
int InsTree (
            int bufnum,
            int h )
```

Definition at line 355 of file comtool.c.

4.15.2.10 FindTree()

```
int FindTree (
            int bufnum,
            WORD * subexpr )
```

Definition at line 533 of file comtool.c.

4.15.2.11 RedoTree()

```
void RedoTree (
            CBUF * C,
            int size )
```

Definition at line 569 of file comtool.c.

4.15.2.12 ClearTree()

```
void ClearTree (
            int i )
```

Definition at line 588 of file comtool.c.

4.15.2.13 IniFbuffer()

```
int IniFbuffer (
            WORD bufnum )
```

Initialize a factorization cache buffer. We set the size of the rhs and boomlijst buffers immediately to their final values.

Definition at line 614 of file comtool.c.

References tree::blnce, CbUf::boomlijst, CbUf::CanCommu, CbUf::dimension, tree::left, CbUf::numdum, CbUf::NumTerms, tree::parent, CbUf::rhs, tree::right, tree::usage, and tree::value.

4.15.2.14 numcommute()

```
LONG numcommute (
            WORD * terms,
            LONG * numterms )
```

Definition at line 659 of file comtool.c.

4.16 comtool.c

    #] AddNtoC :
    #[ InsTree :

    Routines for balanced tree searching and insertion.
    Compared to Knuth we have a parent link. This minimizes the
    number of compares. That is better for anything that is more
    complicated than just single numbers.
    There are no provisions for removing elements from the tree.
    The routines are:
    void RedoTree(size) Re-allocates the tree space. There will
                        be MaxTreeSize = size elements.
    void ClearTree()    Prunes the tree down to the root element.
    int InsTree(int,int)Searches for the requested element. If not found it
                        will allocate a new element, balance the tree if
                        necessary and return the called number.
                        If it was in the tree, it returns the tree 'value'.

    Commentary: added the bufnum on 14-sep-2010 to make the whole a bit
    more flexible (JV).

4.19.1 Detailed Description

Contains macros and function declarations.

Definition in file declare.h.

4.19.2 Macro Definition Documentation

4.19.2.1 MaX

```
#define MaX(
            x,
            y ) ((x) > (y) ? (x): (y))
```

Definition at line 40 of file declare.h.

4.19.2.2 MiN

```
#define MiN(
            x,
            y ) ((x) < (y) ? (x): (y))
```

Definition at line 41 of file declare.h.

4.19.2.3 ABS

```
#define ABS(
            x ) ( (x) < 0 ? -(x): (x) )
```

Definition at line 42 of file declare.h.

4.19.2.4 SGN

```
#define SGN(
            x ) ( (x) > 0 ? 1 : (x) < 0 ? -1 : 0 )
```

Definition at line 43 of file declare.h.

4.19.2.5 REDLENG

```
#define REDLENG(
            x ) ((((x)<0)?((x)+1):((x)-1))>>1)
```

Definition at line 44 of file declare.h.

4.19.2.6 INCLENG

```
#define INCLENG(
            x ) (((x)<0)?(((x)<<1)-1):(((x)<<1)+1))
```

Definition at line 45 of file declare.h.

4.19.2.7 GETCOEF

```
#define GETCOEF(
            x,
            y ) x += *x;y = x[-1];x -= ABS(y);y=REDLENG(y)
```

Definition at line 46 of file declare.h.

4.19.2.8 GETSTOP

```
#define GETSTOP(
            x,
            y ) y=x+(*x)-1;y -= ABS(*y)-1
```

Definition at line 47 of file declare.h.

4.19.2.9 StuffAdd

```
#define StuffAdd(
            x,
            y ) (((x)<0?-1:1)*(y)+((y)<0?-1:1)*(x))
```

Definition at line 48 of file declare.h.

4.19.2.10 TOKENTOLINE

```
#define TOKENTOLINE(
            x,
            y )
```

Value:

```
if ( AC.OutputSpaces == NOSPACEFORMAT ) { \
TokenToLine((UBYTE *)(y)); } else { TokenToLine((UBYTE *)(x)); }
```

Definition at line 50 of file declare.h.

4.19.2.11 UngetFromStream

```
#define UngetFromStream(
            stream,
            c ) ((stream)->nextchar[(stream)->isnextchar++]=c)
```

Definition at line 53 of file declare.h.

4.19.2.12 AddLineFeed

```
#define AddLineFeed(
            s,
            n ) { (s)[(n)++] = LINEFEED; }
```

Definition at line 57 of file declare.h.

4.19.2.13 TryRecover

```
#define TryRecover(
            x ) Terminate(-1)
```

Definition at line 59 of file declare.h.

4.19.2.14 UngetChar

```
#define UngetChar(
            c ) { pushbackchar = c; }
```

Definition at line 60 of file declare.h.

4.19.2.15 ParseNumber

```
#define ParseNumber(
            x,
            s ) {(x)=0;while(*(s)>='0'&&*(s)<='9')(x)=10*(x)+*(s)++ -'0';}
```

Definition at line 61 of file declare.h.

4.19.2.16 ParseSign

```
#define ParseSign(
            sgn,
            s )
```

Value:

```
{(sgn)=0;while(*(s)=='-'||*(s)=='+'){\
if ( *(s)++ == '-' ) sgn ^= 1;}}
```

Definition at line 62 of file declare.h.

4.19.2.17 ParseSignedNumber

```
#define ParseSignedNumber(
            x,
            s )
```

Value:

```
{ int sgn; ParseSign(sgn,s)\
ParseNumber(x,s) if ( sgn ) x = -x; }
```

Definition at line 64 of file declare.h.

4.19.2.18 NCOPY

```
#define NCOPY(
            s,
            t,
            n ) while ( --n >= 0 ) *s++ = *t++;
```

Definition at line 67 of file declare.h.

4.19.2.19 NCOPYI

```
#define NCOPYI(
              s,
              t,
              n ) while ( --n >= 0 ) *s++ = *t++;
```

Definition at line 70 of file declare.h.

4.19.2.20 NCOPYB

```
#define NCOPYB(
              s,
              t,
              n ) while ( --n >= 0 ) *s++ = *t++;
```

Definition at line 71 of file declare.h.

4.19.2.21 NCOPYI32

```
#define NCOPYI32(
              s,
              t,
              n ) while ( --n >= 0 ) *s++ = *t++;
```

Definition at line 72 of file declare.h.

4.19.2.22 WCOPY

```
#define WCOPY(
              s,
              t,
              n ) { int nn=n; WORD *ss=(WORD *)s, *tt=(WORD *)t; while ( --nn >= 0 ) *ss++=*tt++;
}
```

Definition at line 73 of file declare.h.

4.19.2.23 NeedNumber

```
#define NeedNumber(
              x,
              s,
              err )
```

Value:

```
        { int sgn = 1;                                  \
        while ( *s == ' ' || *s == '\t' || *s == '-' || *s == '+' ) {     \
            if ( *s == '-' ) sgn = -sgn; s++; }                           \
        if ( chartype[*s] != 1 ) goto err;                                \
        ParseNumber(x,s)                                                  \
        if ( sgn < 0 ) (x) = -(x); while ( *s == ' ' || *s == '\t' ) s++;\
    }
```

Definition at line 74 of file declare.h.

4.19.2.24 SKIPBLANKS

```
#define SKIPBLANKS(
              s ) { while ( *(s) == ' ' || *(s) == '\t' ) (s)++; }
```

Definition at line 81 of file declare.h.

4.19.2.25 FLUSHCONSOLE

```
#define FLUSHCONSOLE if ( AP.InOutBuf > 0 ) CharOut(LINEFEED)
```

Definition at line 82 of file declare.h.

4.19.2.26 SKIPBRA1

```
#define SKIPBRA1(
              s )
```

Value:

```
{ int lev1=0; s++; while(*s) { if(*s=='[')lev1++; \
else if(*s==']'&&--lev1<0)break; s++;} }
```

Definition at line 84 of file declare.h.

4.19.2.27 SKIPBRA2

```
#define SKIPBRA2(
              s )
```

Value:

```
{ int lev2=0; s++; while(*s) { if(*s=='{')lev2++; \
else if(*s=='}'&&--lev2<0)break; \
else if(*s=='[')SKIPBRA1(s) s++;} }
```

Definition at line 86 of file declare.h.

4.19.2.28 SKIPBRA3

```
#define SKIPBRA3(
              s )
```

Value:

```
{ int lev3=0; s++; while(*s) { if(*s=='(')lev3++; \
else if(*s==')'&&--lev3<0)break; \
else if(*s=='{')SKIPBRA2(s) \
else if(*s=='[')SKIPBRA1(s) s++;} }
```

Definition at line 89 of file declare.h.

4.19.2.29 SKIPBRA4

```
#define SKIPBRA4(
            s )
```

Value:

```
{ int lev4=0; s++; while(*s) { if(*s=='(')lev4++; \
else if(*s==')'&&--lev4<0)break; \
else if(*s=='[')SKIPBRA1(s) s++;} }
```

Definition at line 93 of file declare.h.

4.19.2.30 SKIPBRA5

```
#define SKIPBRA5(
            s )
```

Value:

```
{ int lev5=0; s++; while(*s) { if(*s=='{')lev5++; \
else if(*s=='}'&&--lev5<0)break; \
else if(*s=='(')SKIPBRA4(s) \
else if(*s=='[')SKIPBRA1(s) s++;} }
```

Definition at line 96 of file declare.h.

4.19.2.31 CYCLE1

```
#define CYCLE1(
            t,
            a,
            i ) {t iX=*a; WORD jX; for(jX=1;jX<i;jX++)a[jX-1]=a[jX]; a[i-1]=iX;}
```

Definition at line 104 of file declare.h.

4.19.2.32 AddToCB

```
#define AddToCB(
            c,
            wx )
```

Value:

```
if(c->Pointer>=c->Top) \
DoubleCbuffer(c-cbuf,c->Pointer,21); \
*(c->Pointer)++ = wx;
```

Definition at line 106 of file declare.h.

4.19.2.33 EXCHINOUT

```
#define EXCHINOUT
```

Value:

```
{ FILEHANDLE *ffFi = AR.outfile; \
AR.outfile = AR.infile; AR.infile = ffFi; }
```

Definition at line 110 of file declare.h.

4.19.2.34 BACKINOUT

```
#define BACKINOUT
```

Value:

```
{ FILEHANDLE *ffFi = AR.outfile; POSITION posi; \
AR.outfile = AR.infile; AR.infile = ffFi; \
SetEndScratch(AR.infile,&posi); }
```

Definition at line 112 of file declare.h.

4.19.2.35 CopyArg

```
#define CopyArg(
            to,
            from )
```

Value:

```
{ if ( *from > 0 ) { int ica = *from; NCOPY(to,from,ica) } \
else if ( *from <= -FUNCTION ) *to++ = *from++;  \
else { *to++ = *from++; *to++ = *from++; } }
```

Definition at line 116 of file declare.h.

4.19.2.46 NEXTARG

```
#define NEXTARG(
              x ) if(*x>0) x += *x; else if(*x <= -FUNCTION)x++; else x += 2;
```

Definition at line 160 of file declare.h.

4.19.2.47 COPY1ARG

```
#define COPY1ARG(
              s1,
              t1 )
```

Value:

```
        { int ica; if ( (ica=*t1) > 0 ) { NCOPY(s1,t1,ica) } \
        else if(*t1<=-FUNCTION){*s1++=*t1++;} else{*s1++=*t1++;*s1++=*t1++;} }
```

Definition at line 161 of file declare.h.

4.19.2.48 ZeroFillRange

```
#define ZeroFillRange(
              w,
              begin,
              end )
```

Value:

```
    do { \
    int tmp_i; \
    for ( tmp_i = begin; tmp_i < end; tmp_i++ ) { (w)[tmp_i] = 0; } \
} while (0)
```

Fills a buffer by zero in the range [begin,end).

Parameters

w	The buffer.
begin	The index for the beginning of the range.
end	The index for the end of the range (exclusive).

Definition at line 171 of file declare.h.

4.19.2.49 TABLESIZE

4.19.4.1 TELLFILE()

```
VOID TELLFILE (
            int handle,
            POSITION * position )  [extern]
```

Definition at line 1334 of file tools.c.

4.19.4.2 StartVariables()

```
VOID StartVariables ( )  [extern]
```

All functions (well, nearly all) are declared here.

Definition at line 828 of file startup.c.

References AddNtoC(), AddRHS(), Compare1(), inicbufs(), FuNcTiOn::name, PF_BroadcastNumber(), PutPreVar(), and FuNcTiOn::symmetric.

Here is the call graph for this function:

4.19.4.3 CodeToLine()

```
UBYTE * CodeToLine (
            WORD number,
            UBYTE * Out )  [extern]
```

Definition at line 669 of file sch.c.

4.19.4.4 AddArrayIndex()

```
UBYTE * AddArrayIndex (
            WORD num,
            UBYTE * out )  [extern]
```

Definition at line 707 of file sch.c.

4.19.4.5 FindInIndex()

```
INDEXENTRY * FindInIndex (
            WORD expr,
            FILEDATA * f,
            WORD par,
            WORD mode )  [extern]
```

Definition at line 2644 of file store.c.

4.19.4.6 NextFileIndex()

```
INDEXENTRY * NextFileIndex (
            POSITION * indexpos )  [extern]
```

Definition at line 2237 of file store.c.

4.19.4.7 PasteTerm()

```
WORD * PasteTerm (
            PHEAD WORD number,
            WORD * accum,
            WORD * position,
            WORD times,
            WORD divby )  [extern]
```

Puts the term at position in the accumulator accum at position 'number+1'. if times $>$ 0 the coefficient of this term is multiplied by times/divby.

Parameters

number	The number of term fragments in accum that should be skipped
accum	The accumulator of term fragments
position	A position in (typically) a compiler buffer from where a (piece of a) term comes.
times	Multiply the result by this
divby	Divide the result by this.

This routine is typically used when we have to replace a (sub)expression pointer by a power of a (sub)expression. This uses mostly a binomial expansion and the new term is the old term multiplied one by one by terms of the new expression. The factors times and divby keep track of the binomial coefficient. Once this is complete, the routine FiniTerm will make the contents of the accumulator into a proper term that still needs to be normalized.

Definition at line 2772 of file proces.c.

```
VOID AddArgs (
            PHEAD WORD * s1,
            WORD * s2,
            WORD * m )  [extern]
```

Adds the arguments of two occurrences of the PolyFun.

Parameters

s1	Pointer to the first occurrence.
s2	Pointer to the second occurrence.
m	Pointer to where the answer should be.

Definition at line 2224 of file sort.c.

Referenced by AddPoly(), and MergePatches().

4.19.4.12 AddCoef()

```
WORD AddCoef (
            PHEAD WORD ** ps1,
            WORD ** ps2 )  [extern]
```

Adds the coefficients of the terms *ps1 and *ps2. The problem comes when there is not enough space for a new longer coefficient. First a local solution is tried. If this is not succesfull we need to move terms around. The possibility of a garbage collection should not be ignored, as avoiding this costs very much extra space which is nearly wasted otherwise.

If the return value is zero the terms cancelled.

The resulting term is left in *ps1.

```

Definition at line 750 of file reken.c.

4.19.4.15 AddPoly()

```
WORD AddPoly (
            PHEAD WORD ** ps1,
            WORD ** ps2 )  [extern]
```

Routine should be called when S->PolyWise != 0. It points then to the position of AR.PolyFun in both terms.

We add the contents of the arguments of the two polynomials. Special attention has to be given to special arguments. We have to reserve a space equal to the size of one term + the size of the argument of the other. The addition has to be done in this routine because not all objects are reentrant.

Newer addition (12-nov-2007). The PolyFun can have two arguments. In that case S->PolyFlag is 2 and we have to call the routine for adding rational polynomials. We have to be rather careful what happens with: The location of the output The order of the terms in the arguments At first we allow only univariate polynomials in the PolyFun. This restriction will be lifted a.s.a.p.

Parameters

ps1	A pointer to the postion of the first term
ps2	A pointer to the postion of the second term

Returns

If zero the terms cancel. Otherwise the new term is in *ps1.

            PHEAD WORD * term1,
            WORD * term2,
            WORD level )  [extern]
```

Compares two terms. The answer is: 0 equal (with exception of the coefficient if level == 0.) >0 term1 comes first. <0 term2 comes first. Some special precautions may be needed to keep the CompCoef routine from generating overflows, although this is very unlikely in subterms. This routine should not return an error condition.

Originally this routine was called Compare. With the treatment of special polynomials with terms that contain only symbols and the need for extreme speed for the polynomial routines we made a special compare routine and now we store the address of the current compare routine in AR.CompareRoutine and have a macro Compare which makes all existing code work properly and we can just replace the routine on a thread by thread basis (each thread has its own AR struct).

Parameters

term1	First input term
term2	Second input term
level	The sorting level (may influence on the result)

Returns

0 equal (with exception of the coefficient if level == 0.) >0 term1 comes first. <0 term2 comes first.

Definition at line 2509 of file sort.c.

4.19.4.39 Deferred()

```
WORD Deferred (
            PHEAD WORD * term,
            WORD level )  [extern]
```

Picks up the deferred brackets. These are the bracket contents of which we postpone the reading when we use the 'Keep Brackets' statement. These contents are multiplying the terms just before they are sent to the sorting system. Special attention goes to having it thread-safe We have to lock positioning the file and reading it in a thread specific buffer.

Parameters

term	The term that must be multiplied by the contents of the current bracket
level	The compiler level. This is needed because after multiplying term by term we call Generator again.

            WORD * aa,
            WORD level,
            WORD * freeze )  [extern]
```

Routine gets one power of an expression in the scratch system. If there are more powers needed there will be a recursion.

No attempt is made to use binomials because we have no information about commutating properties.

There is a searching for the contents of brackets if needed. This searching may be rather slow because of the single links.

Parameters

term	is the term we are adding to.
power	is the power of the expression that we need.
nexp	is the number of the expression.
accum	is the accumulator of terms. It accepts the termfragments that are made into a proper term in FiniTerm
aa	points to the start of the entire accumulator. In ∗aa we store the number of term fragments that are in the accumulator.
level	is the current depth in the tree of statements. It is needed to continue to the next operation/substitution with each generated term
freeze	is the pointer to the bracket information that should be matched.

Definition at line 4304 of file proces.c.

4.19.4.76 EndSort()

```
LONG EndSort (
            PHEAD WORD * buffer,
            int par )  [extern]
```

Finishes a sort. At AR.sLevel == 0 the output is to the regular output stream. When AR.sLevel > 0, the parameter par determines the actual output. The AR.sLevel will be popped. All ongoing stages are finished and if the sortfile is open it is closed. The statistics are printed when AR.sLevel == 0 par == 0 Output to the buffer. par == 1 Sort for function arguments. The output will be copied into the buffer. It is assumed that this is in the WorkSpace. par == 2 Sort for $-variable. We return the address of the buffer that contains the output in buffer (treated like WORD **). We first catch the output in a file (unless we can intercept things after the small buffer has been sorted) Then we read from the file into a buffer. Only when par == 0 data compression can be attempted at AT.SS==AT.S0.

Parameters

buffer	buffer for output when needed
par	See above

Returns

If negative: error. If positive: number of words in output.

            WORD number,
            WORD tepos )  [extern]
```

Concatenates the contents of the accumulator into a single legal term, which replaces the subexpression pointer

Parameters

term	the input term with the (sub)expression subterm
accum	the accumulator with the term fragments
termout	the location where the output should be written
number	the number of term fragments in the accumulator
tepos	the position of the subterm in term to be replaced

Definition at line 2837 of file proces.c.

4.19.4.93 FlushOut()

```
WORD FlushOut (
            POSITION * position,
            FILEHANDLE * fi,
            int compr )  [extern]
```

Completes output to an output file and writes the trailing zero.

Parameters

position	The position in the file after writing
fi	The file (or its cache)
compr	Indicates whether there should be compression with gzip.

Returns

Regular conventions (OK -> 0).

Definition at line 1724 of file sort.c.

4.19.4.98 Generator()

```
WORD Generator (
            PHEAD WORD * term,
            WORD level )  [extern]
```

The heart of the program. Here the expansion tree is set up in one giant recursion

Parameters

term	the input term. may be overwritten
level	the level in the compiler buffer (number of statement)

Returns

Normal conventions (OK = 0).

The routine looks first whether there are unsubstituted (sub)expressions. If so, one of them gets inserted term by term and the new term is used in a renewed call to Generator. If there are no (sub)expressions, the term is normalized, the compiler level is raised (next statement) and the program looks what type of statement this is. If this is a special statement it is either treated on the spot or the appropriate routine is called. If it is a substitution, the pattern matcher is called (TestMatch) which tells whether there was a match. If so we need to call TestSub again to test for (sub)expressions. If we run out of levels, the term receives a final treatment for modulus calculus and/or brackets and is then sent off to the sorting routines.

```
WORD InFunction (
            PHEAD WORD * term,
            WORD * termout )  [extern]
```

Makes the replacement of the subexpression with the number 'replac' in a function argument. Additional information is passed in some of the AR, AN, AT variables.

Parameters

term	The input term
termout	The output term

Returns

0: everything is fine, Negative: fatal, Positive: error.

Special attention should be given to nested functions!

Definition at line 1969 of file proces.c.

            WORD * position,
            WORD * termout,
            WORD tepos )  [extern]
```

Puts the terms 'term' and 'position' together into a single legal term in termout. replac is the number of the subexpression that should be replaced. It must be a positive term. When action is needed in the argument of a function all terms in that argument are dealt with recursively. The subexpression is sorted. Only one subexpression is done at a time this way.

Parameters

term	the input term
replac	number of the subexpression pointer to replace
extractbuff	number of the compiler buffer replac refers to
position	position from where to take the term in the compiler buffer
termout	the output term
tepos	offset in term where the subexpression is.

Returns

Normal conventions (OK = 0).

Definition at line 817 of file function.c.

4.19.4.122 MergePatches()

```
WORD MergePatches (
            WORD par )  [extern]
```

The general merge routine. Can be used for the large buffer and the file merging. The array S->Patches tells where the patches start S->pStop tells where they end (has to be computed first). The end of a 'line to be merged' is indicated by a zero. If the end is reached without running into a zero or a term runs over the boundary of a patch it is a file merging operation and a new piece from the file is read in.

Parameters

par	If par == 0 the sort is for file -> outputfile. If par == 1 the sort is for large buffer -> sortfile. If par == 2 the sort is for large buffer -> outputfile.

Definition at line 3498 of file sort.c.

            WORD ** accfill,
            RENUMBER renumber,
            WORD * freeze,
            WORD nexpr )  [extern]
```

Gets a term from stored expression expr and puts it in the accumulator at position number. It returns the length of the term that came from file.

Parameters

number	number of partial terms to skip in accum
accum	the accumulator
position	file position from where to get the stored term
accfill	returns tail position in accum
renumber	the renumber struct for the variables in the stored expression
freeze	information about if we need only the contents of a bracket
nexpr	the number of the stored expression

Returns

Normal conventions (OK = 0).

4.19.4.142 PolyFunMul()

```
WORD PolyFunMul (
            PHEAD WORD * term )  [extern]
```

Multiplies the arguments of multiple occurrences of the polyfun. In this routine we do the original PolyFun with one argument only. The PolyRatFun (PolyFunType = 2) is done in a dedicated routine in the file polywrap.cc The new result is written over the old result.

Parameters

term	It contains the input term and later the output.

Returns

Normal conventions (OK = 0).

Definition at line 5035 of file proces.c.

References EndSort(), LowerSortLevel(), NewSort(), and StoreTerm().

Referenced by Generator().

Here is the call graph for this function:

4.19.4.143 PrepPoly()

```
WORD PrepPoly (
            PHEAD WORD * term,
            WORD par )  [extern]
```

Routine checks whether the count of function AR.PolyFun is zero or one. If it is one and it has one scalarlike argument the coefficient of the term is pulled inside the argument. If the count is zero a new function is made with the coefficient as its only argument. The function should be placed at its proper position.

When this function is active it places the PolyFun as last object before the coefficient. This is needed because otherwise the compress algorithm has problems in MergePatches.

The bracket routine should also place the PolyFun at a comparable spot. The compression should then stop at the PolyFun. It doesn't really have to stop when writing the final result but this may be too complicated.

The parameter par tells whether we are at groundlevel or inside a function or dollar variable.

WORD PutBracket (
            PHEAD WORD * termin )  [extern]
```

Definition at line 1030 of file execute.c.

4.19.4.147 PutIn()

```
LONG PutIn (
            FILEHANDLE * file,
            POSITION * position,
            WORD * buffer,
            WORD ** take,
            int npat )  [extern]
```

Reads a new patch from position in file handle. It is put at buffer, anything after take is moved forward. This would be part of a term that hasn't been used yet. Because of this there should be some space before the start of the buffer

Parameters

file	The file system from which to read
position	The position from which to read
buffer	The buffer into which to read
take	The unused tail should be moved before the buffer
npat	The number of the patch. Is needed if the information was compressed with gzip, because each patch has its own independent gzip encoding.

Definition at line 1241 of file sort.c.

References FiLe::handle.

4.19.4.148 PutInStore()

```
WORD PutInStore (
            INDEXENTRY * ind,
            WORD num )  [extern]
```

Definition at line 861 of file store.c.

4.19.4.149 PutOut()

```
WORD PutOut (
            PHEAD WORD * term,
            POSITION * position,
            FILEHANDLE * fi,
            WORD ncomp )  [extern]
```

Routine writes one term to file handle at position. It returns the new value of the position.

NOTE: For 'final output' we may have to index the brackets. See the struct BRACKETINDEX. We should maintain: 1: a list with brackets array with the brackets 2: a list of objects of type BRACKETINDEX. It contains array with either pointers or offsets to the list of brackets. starting positions in the file. The index may be tied to a maximum size. In that case we may have to prune the list occasionally.

Parameters

term	The term to be written
position	The position in the file. Afterwards it is updated
fi	The file (or its cache) to which should be written
ncomp	Information about what type of compression should be used

Definition at line 1387 of file sort.c.

4.19.4.151 RaisPow()

```
WORD RaisPow (
            PHEAD UWORD * a,
            WORD * na,
            UWORD b )  [extern]
```

Definition at line 1218 of file reken.c.

4.19.4.152 RaisPowCached()

```
VOID RaisPowCached (
            PHEAD WORD x,
            WORD n,
            UWORD ** c,
            WORD * nc )  [extern]
```

Computes power x^n and caches the value

4.19.5 Description

Calculates the power x^n and stores the results for caching purposes. The pointer c (i.e., the pointer, and not what it points to) is overwritten. What it points to should not be overwritten in the calling function.

4.19.6 Notes

- Caching is done in AT.small_power[]. This array is extended if necessary.

Definition at line 1286 of file reken.c.

4.19.6.1 RaisPowMod()

```
WORD RaisPowMod (
            WORD x,
            WORD n,
            WORD m )  [extern]
```

Definition at line 1373 of file reken.c.

4.19.6.2 NormalModulus()

```
int NormalModulus (
            UWORD * a,
            WORD * na )  [extern]
```

Brings a modular representation in the range -p/2 to +p/2 The return value tells whether anything was done. Routine made in the general modulus revamp of July 2008 (JV).

Definition at line 1393 of file reken.c.

Referenced by AddCoef(), and MergePatches().

4.19.6.3 GetModInverses()

```
int GetModInverses (
            WORD m1,
            WORD m2,
            WORD * im1,
            WORD * im2 )  [extern]
```

Input m1 and m2, which are relative prime. determines a∗m1+b∗m2 = 1 (and 1 is the gcd of m1 and m2) then a∗m1 = 1 mod m2 and hence im1 = a. and b∗m2 = 1 mod m1 and hence im2 = b. Set m1 = 0∗m1+1∗m2 = a1∗m1+b1∗m2 m2 = 1∗m1+0∗m2 = a2∗m1+b2∗m2 If everything is OK, the return value is zero

4.19.6.21 SplitMerge()

```
VOID SplitMerge (
            PHEAD WORD ** Pointer,
            LONG number )  [extern]
```

Algorithm by J.A.M.Vermaseren (31-7-1988)

Note that AN.SplitScratch and AN.InScratch are used also in GarbHand

Merge sort in memory. The input is an array of pointers. Sorting is done recursively by dividing the array in two equal parts and calling SplitMerge for each. When the parts are small enough we can do the compare and take the appropriate action. An addition is that we look for 'runs'. Sequences that are already ordered. This happens a lot when there is very little action in a module. This made FORM faster by a few percent.

Parameters

Pointer	The array of pointers to the terms to be sorted.
number	The number of pointers in Pointer.

The terms are supposed to be sitting in the small buffer and there is supposed to be an extension to this buffer for

when there are two terms that should be added and the result takes more space than each of the original terms. The notation guarantees that the result never needs more space than the sum of the spaces of the original terms.

4.19.6.36 TestMatch()

```
WORD TestMatch (
            PHEAD WORD * term,
            WORD * level )  [extern]
```

This routine governs the pattern matching. If it decides that a substitution should be made, this can be either the insertion of a right hand side (C->rhs) or the automatic generation of terms as a result of an operation (like trace). The object to be replaced is removed from term and a subexpression pointer is inserted. If the substitution is made more than once there can be more subexpression pointers. Its number is positive as it corresponds to the level at which the C->rhs can be found in the compiler output. The subexpression pointer contains the wildcard substitution information. The power is found in ∗AT.TMout. For operations the subexpression pointer is negative and corresponds to an address in the array AT.TMout. In this array are then the instructions for the routine to be called and its number in the array 'Operations' The format is here: length,functionnumber,length-2 parameters

There is a certain complexity wrt repeat levels. Another complication is the poking of the wildcard values in the subexpression prototype in the compiler buffer. This was how things were done in the past with sequential FORM, but with the advent of TFORM this cannot be maintained. Now, for TFORM we make a copy of it. 7-may-2008 (JV): We cannot yet guarantee that this has been done 100% correctly. There are errors that occur in TFORM only and that may indicate problems.

Definition at line 97 of file pattern.c.

References AddRHS(), EndSort(), Generator(), CbUf::lhs, LowerSortLevel(), and NewSort().

Referenced by Generator().

Here is the call graph for this function:

4.19.6.37 TestSub()

```
WORD TestSub (
            PHEAD WORD * term,
            WORD level )  [extern]
```

TestSub hunts for subexpression pointers. If one is found its power is given in AN.TeSuOut. and the returnvalue is 'expressionnumber'. If the expression number is negative it is an expression on disk.

In addition this routine tries to locate subexpression pointers in functions. It also notices that action must be taken with any of the special functions.

Parameters

term	The term in which TestSub hunts for potential action
level	The number of the 'level' in the compiler buffer.

Returns

The number of the (sub)expression that was encountered.

Other values that are returned are in AN.TeSuOut, AR.TePos, AT.TMbuff, AN.TeInFun, AN.Frozen, AT.TMaddr

The level in the compiler buffer is more or less the number of the statement in the module. Hence it refers to the element in the lhs array.

This routine is one of the most important routines in FORM.

```
WORD WriteInnerTerm (
            WORD * term,
            WORD first )  [extern]
```

Definition at line 1903 of file sch.c.

4.19.6.60 WriteStats()

```
VOID WriteStats (
            POSITION * plspace,
            WORD par )  [extern]
```

Writes the statistics.

Parameters

plspace	The size in bytes currently occupied
par	par = 0 after a splitmerge. par = 1 after merge to sortfile. par = 2 after the sort

current expression is to be found in AR.CurExpr. terms are in S->TermsLeft. S->GenTerms.

Definition at line 91 of file sort.c.

4.19.6.77 PutPreVar()

```
int PutPreVar (
            UBYTE * name,
            UBYTE * value,
            UBYTE * args,
            int mode )  [extern]
```

Inserts/Updates a preprocessor variable in the name administration.

Parameters

name	Character string with the variable name.
value	Character string with a possible value. Special case: if this argument is zero, then we have no value. Note: This is different from having an empty argument! This should only occur when the name starts with a ?
args	Character string with possible arguments.
mode	=0: always create a new name entry, =1: try to do a redefinition if possible.

Returns

Index of used entry in name list.

            UBYTE * s )  [extern]
```

Definition at line 2083 of file pre.c.

4.19.6.182 TheDefine()

```
int TheDefine (
            UBYTE * s,
            int mode )  [extern]
```

Preprocessor assignment. Possible arguments and values are treated and the new preprocessor variable is put into the name administration.

Parameters

s	Pointer to the character string following the preprocessor command.
mode	Bitmask. 0-bit clear: always create a new name entry, 0-bit set: try to redefine an existing name, 1-bit set: ignore preprocessor if/switch status.

Returns

zero: no errors, negative number: errors.

Definition at line 1938 of file pre.c.

4.19.6.269 ComPress()

```
LONG ComPress (
            WORD ** ss,
            LONG * n )  [extern]
```

Gets a list of pointers to terms and compresses the terms. In n it collects the number of terms and the return value of the function is the space that is occupied.

We have to pay some special attention to the compression of terms with a PolyFun. This PolyFun should occur only straight before the coefficient, so we can use the same trick as for the coefficient to sabotage compression of this object (Replace in the history the function pointer by zero. This is safe, because terms that would be identical otherwise would have been added).

Parameters

ss	Array of pointers to terms to be compressed.
n	Number of pointers in ss.

Returns

Total number of words needed for the compressed result.

Definition at line 3041 of file sort.c.

Referenced by EndSort(), and StoreTerm().

4.19.6.270 StageSort()

```
VOID StageSort (
            FILEHANDLE * fout )  [extern]
```

Prepares a stage 4 or higher sort. Stage 4 sorts occur when the sort file contains more patches than can be merged in one pass.

Definition at line 4364 of file sort.c.

References FiLe::handle.

Referenced by EndSort(), and MergePatches().

4.19.6.279 DoubleCbuffer()

```
WORD * DoubleCbuffer (
            int num,
            WORD * w,
            int par )  [extern]
```

Doubles a compiler buffer.

Parameters

num	The ID number for the buffer to be doubled.
w	The pointer to the end (exclusive) of the current buffer. The contents in the range of [cbuf[num].Buffer,w) will be kept.

Definition at line 143 of file comtool.c.

4.19.6.280 AddLHS()

```
WORD * AddLHS (
            int num )  [extern]
```

Adds an LHS to a compiler buffer and returns the pointer to a buffer for the new LHS.

Parameters

num	The ID number for the buffer to get another LHS.

Definition at line 188 of file comtool.c.

References CbUf::lhs, and CbUf::Pointer.

Referenced by AddNtoL().

4.19.6.281 AddRHS()

```
WORD * AddRHS (
            int num,
            int type )  [extern]
```

Adds an RHS to a compiler buffer and returns the pointer to a buffer for the new RHS.

Parameters

num	The ID number for the buffer to get another RHS.
type	If 0, the subexpression tree will be reallocated.

Definition at line 214 of file comtool.c.

References TaBlEs::buffers, TaBlEs::buffersfill, TaBlEs::bufferssize, TaBlEs::bufnum, CbUf::CanCommu, CbUf::dimension, inicbufs(), CbUf::numdum, CbUf::NumTerms, CbUf::Pointer, and CbUf::rhs.

4.19.6.282 AddNtoL()

```
int AddNtoL (
            int n,
            WORD * array )  [extern]
```

Adds an LHS with the given data to the current compiler buffer.

Parameters

n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 288 of file comtool.c.

References AddLHS(), DoubleCbuffer(), CbUf::Pointer, and CbUf::Top.

Here is the call graph for this function:

4.19.6.283 AddNtoC()

```

            int n,
            WORD * array,
            int par )  [extern]
```

Adds the given data to the last LHS/RHS in a compiler buffer.

Parameters

bufnum	The ID number for the buffer where the data will be added.
n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 317 of file comtool.c.

References DoubleCbuffer(), CbUf::Pointer, and CbUf::Top.

            int par )  [extern]
```

Definition at line 2086 of file compcomm.c.

4.19.6.291 DoArgument()

```
int DoArgument (
            UBYTE * s,
            int par )  [extern]
```

Definition at line 1731 of file compcomm.c.

4.19.6.292 ArgFactorize()

```
int ArgFactorize (
            PHEAD WORD * argin,
            WORD * argout )  [extern]
```

Definition at line 2015 of file argument.c.

4.19.6.293 TakeArgContent()

```
WORD * TakeArgContent (
            PHEAD WORD * argin,
            WORD * argout )  [extern]
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. The common pieces are put in argout as a sequence of arguments. The part with the multiple terms that are now relative prime is put in argfree which is allocated via TermMalloc and is given as the return value. The difference with the old code is that negative powers are always removed. Hence it is as in MakeInteger in which only numerators will be left: now only zero or positive powers will be remaining.

Definition at line 2716 of file argument.c.

References EndSort(), MakeInteger(), MakeMod(), NewSort(), and StoreTerm().

Here is the call graph for this function:

4.19.6.294 MakeInteger()

```
WORD * MakeInteger (
            PHEAD WORD * argin,
            WORD * argout,
            WORD * argfree )  [extern]
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in argin. The number that comes out should go to argout. The new pointer in the argout buffer is the return value. The normalized argument is in argfree.

Definition at line 3262 of file argument.c.

Referenced by TakeArgContent().

4.19.6.295 MakeMod()

```
WORD * MakeMod (
            PHEAD WORD * argin,
            WORD * argout,
            WORD * argfree )  [extern]
```

Similar to MakeInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3433 of file argument.c.

References GetModInverses().

Referenced by TakeArgContent().

Here is the call graph for this function:

4.19.6.296 FindArg()

```
WORD FindArg (
            PHEAD WORD * a )  [extern]
```

Looks the argument up in the (workers) table. If it is found the number in the table is returned (plus one to make it positive). If it is not found we look in the compiler provided table. If it is found - the number in the table is returned (minus one to make it negative). If in neither table we return zero.

Definition at line 2463 of file argument.c.

4.19.6.297 InsertArg()

```
WORD InsertArg (
            PHEAD WORD * argin,
            WORD * argout,
            int par )  [extern]
```

Inserts the argument into the (workers) table. If the table is too full we eliminate half of it. The eliminated elements are the ones that have not been used most recently, weighted by their total use and age(?). If par == 0 it inserts in the regular factorization cache If par == 1 it inserts in the cache defined with the FactorCache statement

Definition at line 2487 of file argument.c.

References AddNtoC(), AddRHS(), and CleanupArgCache().

Here is the call graph for this function:

4.19.6.298 CleanupArgCache()

```
int CleanupArgCache (
            PHEAD WORD bufnum )  [extern]
```

Cleans up the argument factorization cache. We throw half the elements. For a weight of what we want to keep we use the product of usage and the number in the buffer.

Definition at line 2522 of file argument.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::Pointer, CbUf::rhs, SortWeights(), and tree::usage.

int CoElseIf (
            UBYTE * inp )  [extern]
```

Definition at line 4731 of file compcomm.c.

4.19.6.340 CoEndArgument()

```
int CoEndArgument (
            UBYTE * s )  [extern]
```

Definition at line 1972 of file compcomm.c.

4.19.6.341 CoEndInside()

```
int CoEndInside (
            UBYTE * s )  [extern]
```

Definition at line 2005 of file compcomm.c.

4.19.6.342 CoEndIf()

```
int CoEndIf (
            UBYTE * inp )  [extern]
```

Definition at line 4758 of file compcomm.c.

4.19.6.343 CoEndRepeat()

```
int CoEndRepeat (
            UBYTE * inp )  [extern]
```

Definition at line 3635 of file compcomm.c.

4.19.6.344 CoEndTerm()

```
int CoEndTerm (
            UBYTE * s )  [extern]
```

Definition at line 5098 of file compcomm.c.

4.19.6.345 CoEndWhile()

```
int CoEndWhile (
            UBYTE * inp )  [extern]
```

Definition at line 4824 of file compcomm.c.

4.19.6.346 CoExit()

```
int CoExit (
            UBYTE * s )  [extern]
```

Definition at line 3105 of file compcomm.c.

4.19.6.347 CoFactArg()

```
int CoFactArg (
            UBYTE * s )  [extern]
```

Definition at line 2066 of file compcomm.c.

4.19.6.348 CoFactDollar()

```
int CoFactDollar (
            UBYTE * inp )  [extern]
```

Definition at line 6237 of file compcomm.c.

4.19.6.349 CoFactorize()

```
int CoFactorize (
            UBYTE * s )  [extern]
```

Definition at line 6266 of file compcomm.c.

4.19.6.350 CoNFactorize()

```
int CoNFactorize (
            UBYTE * s )  [extern]
```

Definition at line 6273 of file compcomm.c.

4.19.6.351 CoUnFactorize()

```
int CoUnFactorize (
            UBYTE * s )  [extern]
```

Definition at line 6280 of file compcomm.c.

4.19.6.352 CoNUnFactorize()

```
int CoNUnFactorize (
            UBYTE * s )  [extern]
```

Definition at line 6287 of file compcomm.c.

4.19.6.353 DoFactorize()

```
int DoFactorize (
            UBYTE * s,
            int par )  [extern]
```

Definition at line 6294 of file compcomm.c.

4.19.6.354 CoFill()

```
int CoFill (
            UBYTE * inp )  [extern]
```

Definition at line 1063 of file comexpr.c.

4.19.6.355 CoFillExpression()

```
int CoFillExpression (
            UBYTE * inp )  [extern]
```

Definition at line 1339 of file comexpr.c.

4.19.6.356 CoFixIndex()

```
int CoFixIndex (
            UBYTE * s )  [extern]
```

Definition at line 912 of file compcomm.c.

4.19.6.357 CoFormat()

```
int CoFormat (
            UBYTE * s )  [extern]
```

Definition at line 668 of file compcomm.c.

4.19.6.358 CoGlobal()

```
int CoGlobal (
            UBYTE * inp )  [extern]
```

Definition at line 73 of file comexpr.c.

4.19.6.359 CoGlobalFactorized()

```
int CoGlobalFactorized (
            UBYTE * inp )  [extern]
```

Definition at line 87 of file comexpr.c.

4.19.6.360 CoGoTo()

```
int CoGoTo (
            UBYTE * inp )  [extern]
```

Definition at line 1685 of file compcomm.c.

4.19.6.361 CoId()

```
int CoId (
            UBYTE * inp )  [extern]
```

Definition at line 391 of file comexpr.c.

4.19.6.362 CoIdNew()

```
int CoIdNew (
            UBYTE * inp )  [extern]
```

Definition at line 402 of file comexpr.c.

4.19.6.363 CoIdOld()

            WORD ** factor )  [extern]
```

Definition at line 3481 of file dollar.c.

4.19.6.522 MakeDollarInteger()

```
WORD * MakeDollarInteger (
            PHEAD WORD * bufin,
            WORD ** bufout )  [extern]
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in bufin. The number that comes out is the return value. The normalized argument is in bufout.

Definition at line 3533 of file dollar.c.

References EndSort(), Generator(), and NewSort().

Here is the call graph for this function:

4.19.6.523 MakeDollarMod()

```
WORD * MakeDollarMod (
            PHEAD WORD * buffer,
            WORD ** bufout )  [extern]
```

Similar to MakeDollarInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3707 of file dollar.c.

Definition at line 1427 of file dollar.c.

4.19.6.542 EvalDoLoopArg()

```
WORD EvalDoLoopArg (
            PHEAD WORD * arg,
            WORD par )  [extern]
```

Evaluates one argument of a do loop. Such an argument is constructed from SNUMBERs DOLLAREXPRESSIONs and possibly DOLLAREXPR2s which indicate factors of the preceeding dollar. Hence we have SNUMBER,num DOLLAREXPRESSION,numdollar DOLLAREXPRESSION,numdollar,DOLLAREXPR2,numfactor DOLLAREXPRESSION,numdollar,DOLLAREXPR2,numfactor,DOLLAREXPR2,numfactor etc. Because we have a do-loop at every stage we should have a number. The notation in DOLLAREXPR2 is that $>=$ 0 is number of yet another dollar and $<$ 0 is -n-1 with n the array element or zero. The return value is the (short) number. The routine works its way through the list in a recursive manner.

4.19.6.626 CompareSymbols()

```
int CompareSymbols (
            PHEAD WORD * term1,
            WORD * term2,
            WORD par )  [extern]
```

Compares the terms, based on the value of AN.polysortflag. If term1 $<$ term2 the return value is -1 If term1 $>$ term2 the return value is 1 If term1 = term2 the return value is 0 The coefficients may differ. The terms contain only a single subterm of type SYMBOL. If AN.polysortflag = 0 it is a 'regular' compare. If AN.polysortflag = 1 the sum of the powers is more important par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in sort.c

Definition at line 2945 of file sort.c.

Referenced by InFunction(), and TestSub().

4.19.6.627 CompareHSymbols()

```
int CompareHSymbols (
            PHEAD WORD * term1,
            WORD * term2,
            WORD par )  [extern]
```

Compares terms that can have only SYMBOL and HAAKJE subterms. If term1 $<$ term2 the return value is -1 If term1 $>$ term2 the return value is 1 If term1 = term2 the return value is 0 par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in sort.c

Definition at line 2988 of file sort.c.

4.19.6.628 NextPrime()

```
WORD NextPrime (
            PHEAD WORD num )  [extern]
```

Gives the next prime number in the list of prime numbers.

If the list isn't long enough we expand it. For ease in ParForm and because these lists shouldn't be very big we let each worker keep its own list.

The list is cut off at MAXPOWER, because we don't want to get into trouble that the power of a variable gets larger than the prime number.

```
int TreatPolyRatFun (
            PHEAD WORD * prf )  [extern]
```

Definition at line 4795 of file normal.c.

4.19.6.634 ReadSaveIndex()

```
WORD ReadSaveIndex (
            FILEINDEX * fileind )  [extern]
```

Reads a FILEINDEX from the open save file specified by AO.SaveData.Handle. Translations for adjusting endianness and data sizes are done if necessary.

Depends on the assumption that sizeof(FILEINDEX) is the same everywhere. If FILEINDEX or INDEXENTRY change, then this functions has to be adjusted.

Called by CoLoad() and FindInIndex().

Parameters

fileind	contains the read FILEINDEX after succesful return. must point to allocated, big enough memory.

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4137 of file store.c.

References INFILEINDEX, FiLeInDeX::next, FiLeInDeX::number, and FuNcTiOn::number.

4.19.6.635 ReadSaveExpression()

```
WORD ReadSaveExpression (
            UBYTE * buffer,
            UBYTE * top,
            LONG * size,
            LONG * outsize )  [extern]
```

Reads an expression from the open file specified by AO.SaveData.Handle. The endianness flip and a resizing without renumbering is done in this function. Thereafter the buffer consists of chunks with a uniform maximal word

size (32bit at the moment). The actual renumbering is then done by calling the function ReadSaveTerm32(). The result is returned in *buffer*.

If the translation at some point doesn't fit into the buffer anymore, the function returns and must be called again. In any case *size* returns the number of successfully read bytes, *outsize* returns the number of successfully written bytes, and the file will be positioned at the next byte after the successfully read data.

It is called by PutInStore().

Parameters

buffer	output buffer, holds the (translated) expression
top	end of buffer
size	number of read bytes
outsize	number of written bytes

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 5092 of file store.c.

References ReadSaveTerm32().

Here is the call graph for this function:

4.19.6.636 ReadSaveTerm32()

```
UBYTE * ReadSaveTerm32 (
            UBYTE * bin,
            UBYTE * binend,
            UBYTE ** bout,
            UBYTE * boutend,
            UBYTE * top,
            int terminbuf )  [extern]
```

Reads a single term from the given buffer at *bin* and write the translated term back to this buffer at *bout*.

ReadSaveTerm32() is currently the only instantiation of a ReadSaveTerm-function. It only deals with data that already has the correct endianness and that is resized to 32bit words but without being renumbered or translated in any other way. It uses the compress buffer AR.CompressBuffer.

The function is reentrant in order to cope with nested function arguments. It is called by ReadSaveExpression() and itself.

The *return value* indicates the position in the input buffer up to which the data has already been successfully processed. The parameter *bout* returns the corresponding position in the output buffer.

Parameters

bin	start of the input buffer
binend	end of the input buffer
bout	as input points to the beginning of the output buffer, as output points behind the already translated data in the output buffer
boutend	end of already decompressed data in output buffer
top	end of output buffer
terminbuf	flag whether decompressed data is already in the output buffer. used in recursive calls

Returns

pointer to the next unprocessed data in the input buffer

Definition at line 4683 of file store.c.

            LONG * stage )  [extern]
```

Reads the variables from the open file specified by AO.SaveData.Handle. It reads the ∗size bytes and writes them to the ∗buffer. It is called by PutInStore().

If translation is necessary, the data might shrink or grow in size, then ∗*size* is adjusted so that the reading and writing fits into the memory from the buffer to the top. The actual number of read bytes is returned in ∗*size*, the number of written bytes is returned in ∗*outsize*.

If the ∗size is smaller than the actual size of the variables, this function will be called several times and needs to remember the current position in the variable structure. The parameter *stage* does this job. When ReadSaveVariables() is called for the first time, this parameter should have the value -1.

The parameter *ind* is used to get the number of variables.

Parameters

buffer	read variables are written into this allocated memory
top	upper end of allocated memory
size	number of bytes to read. might return a smaller number of read bytes if translation was necessary
outsize	if translation has be done, outsize contains the number of written bytes
ind	pointer of INDEXENTRY for the current expression. read-only
stage	should be -1 for the first call, will be increased by ReadSaveVariables to memorize the position in the variable structure

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4323 of file store.c.

References InDeXeNtRy::nfunctions, InDeXeNtRy::nindices, InDeXeNtRy::nsymbols, InDeXeNtRy::nvectors, and FuNcTiOn::spec.

4.19.6.638 WriteStoreHeader()

```
WORD WriteStoreHeader (
            WORD handle )  [extern]
```

Writes header with information about system architecture and FORM revision to an open store file.

Called by SetFileIndex().

Parameters

handle	specifies open file to which header will be written

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 3926 of file store.c.

References STOREHEADER::endianness, STOREHEADER::lenLONG, STOREHEADER::lenPOINTER, STOREHEADER::lenPOS, STOREHEADER::lenWORD, STOREHEADER::maxpower, STOREHEADER::sFun, STOREHEADER::sInd, STOREHEADER::sSym, STOREHEADER::sVec, and STOREHEADER::wildoffset.

Referenced by SetFileIndex().

4.19.6.639 DoRecovery()

```
int DoRecovery (
            int * moduletype )  [extern]
```

Reads from the recovery file and restores all necessary variables and states in FORM, so that the execution can recommence in preprocessor() as if no restart of FORM had occurred.

The recovery file is read into memory as a whole. The pointer p then points into this memory at the next non-processed data. The macros by which variables are restored, like R_SET, automatically increase p appropriately.

If something goes wrong, the function returns with a non-zero value.

Allocated memory that would be lost when overwriting the global structs with data from the file is freed first. A major part of the code deals with the restoration of pointers. The idiom we use is to memorize the original pointer value (org), allocate new memory and copy the data from the file into this memory, calculate the offset between the old pointer value and the new allocated memory position (ofs), and then correct all affected pointers (+=ofs).

We rely on the fact that several variables (especially in AM) are already assigned the correct values by the startup functions. That means, in principle, that a change in the setup files between snapshot creation and recovery will be noticed.

Definition at line 2115 of file tools.c.

4.19.6.646 TestTerm()

```
int TestTerm (
            WORD * term )  [extern]
```

Tests the consistency of the term. Returns 0 when the term is OK. Any nonzero value is trouble. In the current version the testing isn't 100% complete. For instance, we don't check the validity of the symbols nor do we check the range of their powers. Etc. This should be extended when the need is there.

Parameters

term	the term to be tested

Definition at line 3729 of file tools.c.

References TestTerm().

Referenced by TestTerm().

            WORD startebuf,
            WORD par )  [extern]
```

Converts a generic term to polynomial notation in which there are only symbols and brackets. During conversion there will be only symbols. Brackets are stripped. Objects that need 'translation' are put inside a special compiler buffer and represented by a symbol. The numbering of the extra symbols is down from the maximum. In principle there can be a problem when running into the already assigned ones. This uses the FindTree for searching in the global tree and then looks further in the AT.ebufnum. This allows fully parallel processing. Hence we need no locks. Cannot be used in the same module as ConvertToPoly.

Definition at line 510 of file notation.c.

4.19.6.670 ConvertFromPoly()

```
WORD * TakeSymbolContent (
            PHEAD WORD * in,
            WORD * term )  [extern]
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. We allow only symbols as this code is used for the polyratfun only. We have a special routine, because the generic TakeContent does too much work and speed is at a premium here. Input: in is the input expression as a sequence of terms. Output: term: the content return value: the contentfree expression. it is in new allocation, made by TermMalloc. (should be in a TermMalloc space?)

```
WORD * TakeContent (
            PHEAD WORD * in,
            WORD * term )  [extern]
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. Here the input is a sequence of terms in 'in' and the answer is a content-free sequence of terms. This sequence has been allocated by the Malloc1 routine in a call to EndSort, unless the expression was already content-free. In that case the input pointer is returned. The content is returned in term. This is supposed to be a separate allocation, made by TermMalloc in the calling routine.

```

Definition at line 299 of file dict.c.

4.19.6.727 FindFunction()

```
UBYTE * FindFunction (
            WORD num )  [extern]
```

Definition at line 321 of file dict.c.

4.19.6.728 FindFunWithArgs()

```
UBYTE * FindFunWithArgs (
            WORD * t )  [extern]
```

Definition at line 343 of file dict.c.

4.19.6.729 FindExtraSymbol()

```
UBYTE * FindExtraSymbol (
            WORD num )  [extern]
```

Definition at line 375 of file dict.c.

4.19.6.730 DictToBytes()

```
LONG DictToBytes (
            DICTIONARY * dict,
            UBYTE * buf )  [extern]
```

Definition at line 1117 of file dict.c.

4.19.6.731 DictFromBytes()

```
DICTIONARY * DictFromBytes (
            UBYTE * buf )  [extern]
```

Definition at line 1150 of file dict.c.

4.19.6.732 CoCreateSpectator()

```
int CoCreateSpectator (
            UBYTE * inp )  [extern]
```

Definition at line 89 of file spectator.c.

4.19.6.733 CoToSpectator()

```
int CoToSpectator (
            UBYTE * inp )  [extern]
```

Definition at line 181 of file spectator.c.

4.19.6.734 CoRemoveSpectator()

```
int CoRemoveSpectator (
            UBYTE * inp )  [extern]
```

Definition at line 233 of file spectator.c.

4.19.6.735 CoEmptySpectator()

```
int CoEmptySpectator (
            UBYTE * inp )  [extern]
```

Definition at line 289 of file spectator.c.

4.19.6.736 CoCopySpectator()

```
int CoCopySpectator (
            UBYTE * inp )  [extern]
```

Definition at line 455 of file spectator.c.

4.19.6.737 PutInSpectator()

```
int PutInSpectator (
            WORD * term,
            WORD specnum )  [extern]
```

Definition at line 341 of file spectator.c.

4.19.6.738 ClearSpectators()

```
void ClearSpectators (
            WORD par )  [extern]
```

Definition at line 667 of file spectator.c.

4.19.6.739 GetFromSpectator()

```
WORD GetFromSpectator (
            WORD * term,
            WORD specnum )  [extern]
```

Definition at line 593 of file spectator.c.

4.19.6.740 FlushSpectators()

```
void FlushSpectators (
            VOID  )  [extern]
```

Definition at line 398 of file spectator.c.

4.19.6.741 ReadFromScratch()

```
int ReadFromScratch (
            FILEHANDLE * fi,
            POSITION * pos,
            UBYTE * buffer,
            POSITION * length )  [extern]
```

Definition at line 273 of file store.c.

4.19.6.742 AddToScratch()

```
int AddToScratch (
            FILEHANDLE * fi,
            POSITION * pos,
            UBYTE * buffer,
            POSITION * length,
            int withflush )  [extern]
```

Definition at line 300 of file store.c.

4.19.6.743 DoPreAppendPath()

```
int DoPreAppendPath (
            UBYTE * s )  [extern]
```

Appends the given path (absolute or relative to the current file directory) to the FORM path.

Syntax: #appendpath <path>

Definition at line 6875 of file pre.c.

4.19.6.744 DoPrePrependPath()

```
int DoPrePrependPath (
            UBYTE * s )  [extern]
```

Prepends the given path (absolute or relative to the current file directory) to the FORM path.

Syntax: #prependpath <path>

Definition at line 6892 of file pre.c.

4.21.1 Detailed Description

Contains the code pertaining to dictionaries Commands are: #opendictionary name #closedictionary #selectdictionary name <options> There can be several dictionaries, but only one can be active. Defining elements is done with #add object: "replacement" Replacements are strings when a dictionary is for output translation. Objects can be 1: a number (rational) 2: a variable 3: ∗ ^ 4: a function with arguments

Definition in file dict.c.

4.21.2 Function Documentation

4.21.2.1 TransformRational()

```
VOID TransformRational (
            UWORD * a,
            WORD na )
```

Definition at line 71 of file dict.c.

4.21.2.2 IsMultiplySign()

```
int IsMultiplySign (
            VOID  )
```

Definition at line 218 of file dict.c.

4.21.2.3 IsExponentSign()

```
int IsExponentSign (
            VOID  )
```

Definition at line 237 of file dict.c.

4.21.2.4 FindSymbol()

```
UBYTE * FindSymbol (
            WORD num )
```

Definition at line 256 of file dict.c.

4.21.2.5 FindVector()

```
UBYTE * FindVector (
            WORD num )
```

Definition at line 277 of file dict.c.

4.21.2.6 FindIndex()

```
UBYTE * FindIndex (
            WORD num )
```

Definition at line 299 of file dict.c.

4.21.2.7 FindFunction()

```
UBYTE * FindFunction (
            WORD num )
```

Definition at line 321 of file dict.c.

4.21.2.8 FindFunWithArgs()

```
UBYTE * FindFunWithArgs (
            WORD * t )
```

Definition at line 343 of file dict.c.

4.21.2.9 FindExtraSymbol()

```
UBYTE * FindExtraSymbol (
            WORD num )
```

Definition at line 375 of file dict.c.

4.21.2.10 FindDictionary()

```
int FindDictionary (
            UBYTE * name )
```

Definition at line 432 of file dict.c.

4.21.2.11 AddDictionary()

```
int AddDictionary (
            UBYTE * name )
```

Definition at line 447 of file dict.c.

4.21.2.12 AddToDictionary()

```
int AddToDictionary (
            DICTIONARY * dict,
            UBYTE * left,
            UBYTE * right )
```

Definition at line 489 of file dict.c.

4.21.2.13 UseDictionary()

```
int UseDictionary (
            UBYTE * name,
            UBYTE * options )
```

Definition at line 764 of file dict.c.

4.21.2.14 SetDictionaryOptions()

```
int SetDictionaryOptions (
            UBYTE * options )
```

Definition at line 788 of file dict.c.

4.21.2.15 UnSetDictionary()

```
void UnSetDictionary (
            VOID  )
```

Definition at line 881 of file dict.c.

4.21.2.16 RemoveDictionary()

```
void RemoveDictionary (
            DICTIONARY * dict )
```

Definition at line 900 of file dict.c.

4.21.2.17 ShrinkDictionary()

```
void ShrinkDictionary (
            DICTIONARY * dict )
```

Definition at line 943 of file dict.c.

4.21.2.18 DoPreOpenDictionary()

```
int DoPreOpenDictionary (
            UBYTE * s )
```

Definition at line 957 of file dict.c.

4.21.2.19 DoPreCloseDictionary()

```
int DoPreCloseDictionary (
            UBYTE * s )
```

Definition at line 996 of file dict.c.

4.21.2.20 DoPreUseDictionary()

```
int DoPreUseDictionary (
            UBYTE * s )
```

Definition at line 1020 of file dict.c.

4.21.2.21 DoPreAdd()

```
int DoPreAdd (
            UBYTE * s )
```

Definition at line 1065 of file dict.c.

4.21.2.22 DictToBytes()

```
LONG DictToBytes (
            DICTIONARY * dict,
            UBYTE * buf )
```

Definition at line 1117 of file dict.c.

4.21.2.23 DictFromBytes()

```
DICTIONARY * DictFromBytes (
            UBYTE * buf )
```

Definition at line 1150 of file dict.c.

4.22 dict.c

4.23.1 Detailed Description

The routines that deal with the dollar variables. The name administration is to be found in the file names.c

Definition in file dollar.c.

4.23.2 Macro Definition Documentation

4.23.2.1 STEP2

```
#define STEP2
```

Factors a dollar expression. Notation: d->nfactors becomes nonzero. if the number of factors is one, we leave d->factors zero. Otherwise factors is an array of pointers to the factors. These are pointers of the type FACDOLLAR. fd->where pointer to contents in term notation fd->size size of the buffer fd->where points to fd->type DOLNUMBER or DOLTERMS fd->value value if type is DOLNUMBER and it fits in a WORD.

Definition at line 2859 of file dollar.c.

4.23.3 Function Documentation

4.23.3.1 CatchDollar()

```
int CatchDollar (
            int par )
```

Definition at line 54 of file dollar.c.

4.23.3.2 AssignDollar()

```
int AssignDollar (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 209 of file dollar.c.

4.23.3.3 WriteDollarToBuffer()

```

4.23.3.25 DollarRaiseLow()

```
int DollarRaiseLow (
            UBYTE * name,
            LONG value )
```

Definition at line 2458 of file dollar.c.

4.23.3.26 EvalDoLoopArg()

```
WORD EvalDoLoopArg (
            PHEAD WORD * arg,
            WORD par )
```

Evaluates one argument of a do loop. Such an argument is constructed from SNUMBERs DOLLAREXPRESSIONs and possibly DOLLAREXPR2s which indicate factors of the preceeding dollar. Hence we have SNUMBER,num DOLLAREXPRESSION,numdollar DOLLAREXPRESSION,numdollar,DOLLAREXPR2,numfactor DOLLAREXPRESSION,numdollar,DOLLAREXPR2,numfactor,DOLLAREXPR2,numfactor etc. Because we have a do-loop at every stage we should have a number. The notation in DOLLAREXPR2 is that >= 0 is number of yet another dollar and < 0 is -n-1 with n the array element or zero. The return value is the (short) number. The routine works its way through the list in a recursive manner.

Definition at line 2557 of file dollar.c.

4.23.3.27 TestDoLoop()

```
WORD TestDoLoop (
            PHEAD WORD * lhsbuf,
            WORD level )
```

Definition at line 2668 of file dollar.c.

4.23.3.28 TestEndDoLoop()

```
WORD TestEndDoLoop (
            PHEAD WORD * lhsbuf,
            WORD level )
```

Definition at line 2746 of file dollar.c.

4.23.3.29 DollarFactorize()

```
int DollarFactorize (
            PHEAD WORD numdollar )
```

Definition at line 2861 of file dollar.c.

4.23.3.30 CleanDollarFactors()

```
void CleanDollarFactors (
            DOLLARS d )
```

Definition at line 3460 of file dollar.c.

4.23.3.31 TakeDollarContent()

```
WORD * TakeDollarContent (
            PHEAD WORD * dollarbuffer,
            WORD ** factor )
```

Definition at line 3481 of file dollar.c.

4.23.3.32 MakeDollarInteger()

```
WORD * MakeDollarInteger (
            PHEAD WORD * bufin,
            WORD ** bufout )
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in bufin. The number that comes out is the return value. The normalized argument is in bufout.

Definition at line 3533 of file dollar.c.

References EndSort(), Generator(), and NewSort().

Here is the call graph for this function:

4.23.3.33 MakeDollarMod()

```
WORD * MakeDollarMod (
            PHEAD WORD * buffer,
            WORD ** bufout )
```

Similar to MakeDollarInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3707 of file dollar.c.

4.23.3.34 GetDolNum()

```
int GetDolNum (
            PHEAD WORD * t,
            WORD * tstop )
```

Definition at line 3752 of file dollar.c.

4.23.3.35 AddPotModdollar()

```
void AddPotModdollar (
            WORD numdollar )
```

Adds a $-variable specified by *numdollar* to the list of potentially modified $-variables unless it has already been included in the list.

Parameters

numdollar	The index of the $-variable to be added.

Definition at line 3865 of file dollar.c.

/*
        #] DoExecute :
        #[ PutBracket :

    Routine uses the bracket info to split a term into two pieces:
    1: the part outside the bracket, and
    2: the part inside the bracket.
    These parts are separated by a subterm of type HAAKJE.
    This subterm looks like: HAAKJE,3,level
    The level is used for nestings of brackets. The print routines
    cannot handle this yet (31-Mar-1988).

    The Bracket selector is in AT.BrackBuf in the form of a regular term,
    but without coefficient.
    When AR.BracketOn < 0 we have a socalled antibracket. The main effect
    is an exchange of the inner and outer part and where the coefficient goes.

    Routine recoded to facilitate b p1,p2; etc for dotproducts and tensors
    15-oct-1991

00032     #[ Documentation :
00033
00034     This module is written by M.Tentyukov as a part of implementation of
00035     interaction between FORM and external processes, first release
```

```
09.04.2004. A part of this code is copyied from the DIANA project
written by M. Tentyukov and published under the GPL version 2 as
published by the Free Software Foundation.  The code of this module
is NOT covered by GPL; it can be used under the terms of the FORM
License http://www.nikhef.nl/~form/license.html

This file is completely re-written by M.Tentyukov in May 2006.
Since the interface was changed, the public function were changed,
also. A new publc functions were added: initPresetExternalChannels()
(see comments just before this function in the present file) and
setKillModeForExternalChannel (a pointer, not a function).

If a macro WITHEXTERNALCHANNEL is not defined, all public punctions
are stubs returning failure.

The idea is to start an external command  swallowing
its stdin and stdout. This can be done by means of the function
int openExternalChannel(cmd,daemonize,shellname,stderrname), where
cmd is a command to run,
daemonize: if !=0 then start the command in the "daemon" mode,
shellname: if !=NULL, execute the command in a subshell,
stderrname: if != NULL, redirect stderr of the command to this file.
The function returns some small positive integer number (the
descriptor of a newly created external channel), or -1 on failure.

After the command is started, it becomes a _current_ opened external
channel. The buffer can be sent to its stdin by a function
int writeBufToExtChannel(buf, n)
(here buf is a pointer to the buffer, n is the length in bytes; the
function returns 0 in success, or -1 on failure),
or one character can be read from its stdout by
means of the function
int getcFromExtChannel().

The latter returns the
character casted to integer, or something <0. This can be -2 (if there
is no current external channel) or EOF, if the external program closes
its stdout, or if the external program outputs a string coinciding
with a _terminator_.

By default, the terminator if an empty line. For the current external
channel it can be set by means of the function
int setTerminatorForExternalChannel(newterminaror).
The function returns 0 in success, or !0 if something is wrong (no
current channel, too long terminator).

After getcFromExtChannel() returns EOF, the current channel becomes
undefined. Any further attempts to read information by
getcFromExtChannel() result in -2. To set (re-set) a current channel,
the function
int selectExternalChannel(n)
can be used. This function accepts the valid external channel
descriptor (returned by openExternalChannel) and returns the
descriptor of a previous current channel (0, if there was no current
channel, or -1, if the external channel descriptor is invalid).
If n == 0, the function undefine the current external channel.

The function
int closeExternalChannel(n)
destroys the opened external channel with the descriptor n. It returns
0 in success, or -1 on failure. If the corresponding external channel
was the current one, the current channel becomes undefined. If n==0,
the function closes the current external channel.

The function
int getCurrentExternalChannel(void)
returns the descriptor if the current external channel, or 0 , if
there is no current external channel.

The function
void closeAllExternalChannels(void)

destroys all opened external channels.

List of all public functions:
int openExternalChannel(UBYTE *cmd,int daemonize,UBYTE *shellname, UBYTE * stderrname);
int initPresetExternalChannels(UBYTE *theline, int thetimeout);
int setTerminatorForExternalChannel(char *newterminaror);
int setKillModeForExternalChannel(int signum, int sentToWholeGroup);
int closeExternalChannel(int n);
int selectExternalChannel(int n);
int writeBufToExtChannel(char *buf,int n);
int getcFromExtChannel(void);
int getCurrentExternalChannel(void);
void closeAllExternalChannels(void);

ATTENTION!
```

```

    Four of them:
    1 setTerminatorForExternalChannel
    2 setKillModeForExternalChannel
    3 writeBufToExtChannel
    4 getcFromExtChannel

    are NOT functions, but variables (pointers) of a corrsponding type.
    They are initialised by proper values to avoid repeated error checking.

    All public functions are independent of realization hidden in this module.
    All other functions may have a returned type/parameters type local w.r.t.
    this module; they are not declared outside of this file.

/*
    #] FactorIn :
    #[ FactorInExpr :

    This routine tests for a factor in an active or hidden expression.

    The factor from the last call is stored in a cache.
    Main problem here is whether the cache is global or private to each thread.
    A global cache gives most likely the same traffic jam for the computation
    as a local cache. The local cache may stay valid longer.
    In the future we may make it such that threads can look at the cache
    of the others, or even whether a certain factor is under construction.

4.31.1 Detailed Description

Pattern matching of symbols and dotproducts. There are various routines because of the options in the id-statements like once, only, multi and many. These are amoung the oldest routines in FORM and that can be noticed, because the interplay with the function matching is not complete. When we match functions and halfway we fail we can backtrack properly. With the symbols, the dotproducts and the vectors (in pattern.c) there is no proper backtracking. Hence the routines here need still quite some work or may even have to be rewritten.

4.31.2 Function Documentation

4.31.2.1 FindOnly()

```
WORD FindOnly (
            PHEAD WORD * term,
            WORD * pattern )
```

Definition at line 61 of file findpat.c.

4.31.2.2 FindOnce()

```
WORD FindOnce (
            PHEAD WORD * term,
            WORD * pattern )
```

Definition at line 419 of file findpat.c.

4.31.2.3 FindMulti()

```
WORD FindMulti (
            PHEAD WORD * term,
            WORD * pattern )
```

Definition at line 954 of file findpat.c.

4.31.2.4 FindRest()

```
WORD FindRest (
            PHEAD WORD * term,
            WORD * pattern )
```

Definition at line 1070 of file findpat.c.

00049
00050     The current version doesn't scan function arguments yet. 10-Apr-1988
00051
00052     This routine searches for an exact match. This means in particular:
00053     1:  x^# must match exactly.
00054     2:  x^n? must have a single value for n that cannot be addapted.
00055
00056     When setp != 0 it points to a collection of sets
00057     A match can occur only if no object will be left that belongs
00058     to any of these sets.

/*
 * Macros inserted to the end of a structure to align the whole structure.
 *
 * In the currently available systems,
 *   sizeof(POSITION) >= sizeof(pointers) == sizeof(LONG) >= sizeof(int)
 *                    >= sizeof(WORD) >= sizeof(UBYTE) = 1.
 * (POSITION is defined in struct.h and contains only an off_t variable.)
 * Thus, if we put members of a structure in this order and use those macros,
 * then we can align the data without relying on extra paddings added by
 * the compiler. For example,
 *   typedef struct {
 *     int *a;
 *     LONG b;
 *     WORD c[2];
 *     UBYTE d;
 *     PADPOINTER(1,0,2,1);
 *   } A;
 *   typedef struct {
 *     POSITION p;
 *     A a;  // aligned same as pointers
 *     int *b;
 *     LONG c;
 *     UBYTE d;
 *     PADPOSITION(1,1,0,0,1+sizeof(A));
 *   } B;
 * The cost for the use of those PADXXX functions is a padding (>= 1 byte) will
 * be always inserted even in the case that no padding is actually needed.
 *
 * Note that there is a 32-bit system in which off_t is aligned on 8-byte
 * boundary, (e.g., Cygwin).
 */

4.37.1 Detailed Description

Contains the definitions of many internal codes Rather than using numbers directly we do this by defines, making it much easier to change things. Changing things is sometimes also a good way of testing the code.

Definition in file ftypes.h.

4.37.2 Macro Definition Documentation

4.37.2.1 PHEAD

```
#define PHEAD
```

The next macros were introduced when TFORM was programmed. In the case of workers, each worker may need some private data. These can in principle be accessed by some posix calls but that is unnecessarily slow. The passing of a pointer to the complete data struct with private data will be much faster. And anyway, there would have to be a macro that either makes the posix call (TFORM) or doesn't (FORM). The solution by having macro's that either pass the pointer (TFORM) or don't pass it (FORM) is seen as the best solution.

In the declarations and the calling of the functions we have to use the PHEAD or the BHEAD macro, respectively, if the pointer is to be passed. These macro's contain the comma as well. Hence we need special macro's if there are no other arguments. These are called PHEAD0 and BHEAD0.

4.39.1 Detailed Description

The file with the central routines for the pattern matching of functions and their arguments. The file also contains the routines for the execution of the Symmetrize statement and its variations (like antisymmetrize etc).

Definition in file function.c.

4.39.2 Function Documentation

4.39.2.1 MakeDirty()

```
WORD MakeDirty (
            WORD * term,
            WORD * x,
            WORD par )
```

Definition at line 51 of file function.c.

4.39.2.2 MarkDirty()

```
void MarkDirty (
            WORD * term,
            WORD flags )
```

Definition at line 97 of file function.c.

4.39.2.3 PolyFunDirty()

```
void PolyFunDirty (
            PHEAD WORD * term )
```

Definition at line 139 of file function.c.

4.39.2.4 PolyFunClean()

```
void PolyFunClean (
            PHEAD WORD * term )
```

Definition at line 174 of file function.c.

4.39.2.5 Symmetrize()

```
WORD Symmetrize (
            PHEAD WORD * func,
            WORD * Lijst,
            WORD ngroups,
            WORD gsize,
            WORD type )
```

Definition at line 213 of file function.c.

4.39.2.6 CompGroup()

```
WORD CompGroup (
            PHEAD WORD type,
            WORD ** args,
            WORD * a1,
            WORD * a2,
            WORD num )
```

Definition at line 373 of file function.c.

4.39.2.7 FullSymmetrize()

```
int FullSymmetrize (
            PHEAD WORD * fun,
            int type )
```

Definition at line 473 of file function.c.

4.39.2.8 SymGen()

```
WORD SymGen (
            PHEAD WORD * term,
            WORD * params,
            WORD num,
            WORD level )
```

Definition at line 518 of file function.c.

4.39.2.9 SymFind()

```
WORD SymFind (
            PHEAD WORD * term,
            WORD * params )
```

Definition at line 633 of file function.c.

4.39.2.10 ChainIn()

```
int ChainIn (
            PHEAD WORD * term,
            WORD funnum )
```

Definition at line 691 of file function.c.

4.39.2.11 ChainOut()

```
int ChainOut (
            PHEAD WORD * term,
            WORD funnum )
```

Definition at line 739 of file function.c.

4.39.2.12 MatchFunction()

```
WORD MatchFunction (
            PHEAD WORD * pattern,
            WORD * interm,
            WORD * wilds )
```

Definition at line 817 of file function.c.

4.39.2.13 ScanFunctions()

```
WORD ScanFunctions (
            PHEAD WORD * inpat,
            WORD * inter,
            WORD par )
```

Definition at line 1604 of file function.c.

/*
        #] SymGen :
        #[ SymFind :

        There is a certain amount of double work here, as this routine
        finds the function to be treated, while the SymGen routine has
        to find it again. Note however that this way things remain
        uniform and simple. Moreover this avoids problems with actions
        on more than one function simultaneously.
        Output in AT.TMout:
        Number,sym/anti,fun,lenpar,ngroups,gsize,fields

/*
        #] ChainOut :
    #] Utilities :
    #[ Patterns :
        #[ MatchFunction :          WORD MatchFunction(pattern,interm,wilds)

        The routine assumes that the function numbers are the same.
        The contents are compared and a possible wildcard assignment
        is made. Note that it may be necessary to use a wildcard
        assignment stack to do things right.
        The routine can become arbitrarily complicated as there is
        no end to the possible wildcarding.
        Examples:
        -   a:  No wildcarding -> straight match
        -   b:  Individual arguments (object -> object)
        -   c:  whole arguments (object to subexpression)
        -   d:  any argumentlist
            e:  part of an argument (object inside subexpression)

        The ones with a minus sign in front have been implemented.

        Note: the argument wilds allows backtracking when multiple
        ?a,?b give a match that later turns out to be useless.
