4.96.2.6 SETBUFSIZE

```
#define SETBUFSIZE 257
```

Definition at line 1088 of file setfile.c.

4.96.3 Function Documentation

4.96.3.1 DoSetups()

```
int DoSetups ( )
```

Definition at line 125 of file setfile.c.

4.96.3.2 ProcessOption()

```
int ProcessOption (
            UBYTE * s1,
            UBYTE * s2,
            int filetype )
```

Definition at line 175 of file setfile.c.

4.96.3.3 GetSetupPar()

```
SETUPPARAMETERS * GetSetupPar (
            UBYTE * s )
```

Definition at line 330 of file setfile.c.

4.96.3.4 RecalcSetups()

```
int RecalcSetups ( )
```

Definition at line 350 of file setfile.c.

4.96.3.5 AllocSetups()

```
int AllocSetups ( )
```

Definition at line 397 of file setfile.c.

4.96.3.6 WriteSetup()

```
VOID WriteSetup ( )
```

Definition at line 780 of file setfile.c.

4.96.3.7 AllocSort()

```
SORTING * AllocSort (
            LONG LargeSize,
            LONG SmallSize,
            LONG SmallEsize,
            LONG TermsInSmall,
            int MaxPatches,

    The routine writes the values of the setup parameters.
    We should do this better. (JV, 21-may-2008)
    The way it should be done is:
        a: write the raw values.
        b: give readjusted values.
        c: give derived values.
    Because this is a difficult subject, it would be nice to have a LaTeX
    document that explains this all exactly. There should then be a
    mechanism to poke the values of the setup into the LaTeX document.
    probably the easiest way is to make a file with lots of \def definitions
    and have that included into the LaTeX file.

Functions

- int StudyPattern (WORD *lhs)
- int MatchIsPossible (WORD *pattern, WORD *term)

4.98.1 Detailed Description

The functions for smart pattern searches in combinations of functions. When many wildcards are involved and the functions are (anti)symmetric an exhaustive search for all possibilities may take very much time (like factorial in the number of wildcards) while a human can often see immediately that there cannot be a match. The routines here try to make FORM a bit smarter in this respect.

This is just the beginning. It still needs lots of work!

4.100.1 Detailed Description

Contains the sort routines. We distinguish levels of sorting. The ground level is the sorting of terms in an expression. When a term has functions, the arguments can contain terms that need sorting, which this then done by raising the level. This can happen recursively. NewSort and EndSort automatically raise and lower the level. Because the ground level does some special things, sometimes we have to raise immediately to the second level skipping the ground level.

Special routines for the parallel sorting are in the file threads.c Also the sorting of terms in polynomials is special but most of that is controled by changing the address of the compare routine. Other routines relevant for adding rational polynomials are in the file polynito.c

4.100.2 Macro Definition Documentation

4.100.2.1 NEWSPLITMERGE

```
#define NEWSPLITMERGE
```

Definition at line 53 of file sort.c.

4.100.2.2 INSLENGTH

```
#define INSLENGTH(
              x ) w[1] = FUNHEAD+ARGHEAD+x; w[FUNHEAD] = ARGHEAD+x;
```

Definition at line 2215 of file sort.c.

4.100.3 Function Documentation

4.100.3.1 WriteStats()

```
VOID WriteStats (
            POSITION * plspace,
            WORD par )
```

Writes the statistics.

Parameters

plspace	The size in bytes currently occupied
par	par = 0 after a splitmerge. par = 1 after merge to sortfile. par = 2 after the sort

current expression is to be found in AR.CurExpr. terms are in S->TermsLeft. S->GenTerms.

Definition at line 91 of file sort.c.

References TimeCPU(), and TimeWallClock().

Referenced by EndSort(), PF_Processor(), and StoreTerm().

Here is the call graph for this function:

4.100.3.2 NewSort()

```
WORD NewSort (
            PHEAD0  )
```

Starts a new sort. At the lowest level this is a 'main sort' with the struct according to the parameters in S0. At higher levels this is a sort for functions, subroutines or dollars. We prepare the arrays and structs.

Returns

Regular convention (OK -> 0)

Definition at line 589 of file sort.c.

Referenced by InFunction(), MakeDollarInteger(), MakeDollarMod(), PF_CollectModifiedDollars(), PF_Processor(), PolyFunMul(), Processor(), TakeArgContent(), TestMatch(), and TestSub().

4.100.3.3 EndSort()

```
LONG EndSort (
            PHEAD WORD * buffer,
            int par )
```

Finishes a sort. At AR.sLevel == 0 the output is to the regular output stream. When AR.sLevel > 0, the parameter par determines the actual output. The AR.sLevel will be popped. All ongoing stages are finished and if the sortfile is open it is closed. The statistics are printed when AR.sLevel == 0 par == 0 Output to the buffer. par == 1 Sort for function arguments. The output will be copied into the buffer. It is assumed that this is in the WorkSpace. par == 2 Sort for $-variable. We return the address of the buffer that contains the output in buffer (treated like WORD **). We first catch the output in a file (unless we can intercept things after the small buffer has been sorted) Then we read from the file into a buffer. Only when par == 0 data compression can be attempted at AT.SS==AT.S0.

Parameters

buffer	buffer for output when needed
par	See above

Returns

If negative: error. If positive: number of words in output.

Definition at line 675 of file sort.c.

References ComPress(), FlushOut(), MergePatches(), PF_EndSort(), PutOut(), SplitMerge(), StageSort(), and WriteStats().

Referenced by InFunction(), MakeDollarInteger(), MakeDollarMod(), PF_CollectModifiedDollars(), PF_Processor(), PolyFunMul(), Processor(), TakeArgContent(), TestMatch(), and TestSub().

Here is the call graph for this function:

4.100.3.4 PutIn()

```
LONG PutIn (
            FILEHANDLE * file,
            POSITION * position,
            WORD * buffer,
            WORD ** take,
            int npat )
```

Reads a new patch from position in file handle. It is put at buffer, anything after take is moved forward. This would be part of a term that hasn't been used yet. Because of this there should be some space before the start of the buffer

Parameters

file	The file system from which to read
position	The position from which to read
buffer	The buffer into which to read
take	The unused tail should be moved before the buffer
npat	The number of the patch. Is needed if the information was compressed with gzip, because each patch has its own independent gzip encoding.

Definition at line 1241 of file sort.c.

References FiLe::handle.

Referenced by MergePatches().

4.100.3.5 Sflush()

```
WORD Sflush (
            FILEHANDLE * fi )
```

Puts the contents of a buffer to output Only to be used when there is a single patch in the large buffer.

Parameters

fi	The filesystem (or its cache) to which the patch should be written

Definition at line 1301 of file sort.c.

References FiLe::handle.

Referenced by MergePatches().

4.100.3.6 PutOut()

```
WORD PutOut (
            PHEAD WORD * term,
            POSITION * position,
            FILEHANDLE * fi,
            WORD ncomp )
```

Routine writes one term to file handle at position. It returns the new value of the position.

NOTE: For 'final output' we may have to index the brackets. See the struct BRACKETINDEX. We should maintain: 1: a list with brackets array with the brackets 2: a list of objects of type BRACKETINDEX. It contains array with either pointers or offsets to the list of brackets. starting positions in the file. The index may be tied to a maximum size. In that case we may have to prune the list occasionally.

Parameters

term	The term to be written
position	The position in the file. Afterwards it is updated
fi	The file (or its cache) to which should be written
ncomp	Information about what type of compression should be used

Definition at line 1387 of file sort.c.

References FiLe::handle, and PF_ISendSbuf().

Referenced by EndSort(), MergePatches(), PF_EndSort(), PF_Processor(), and Processor().

Here is the call graph for this function:

4.100.3.7 FlushOut()

```
WORD FlushOut (
            POSITION * position,
            FILEHANDLE * fi,
            int compr )
```

Completes output to an output file and writes the trailing zero.

Parameters

position	The position in the file after writing
fi	The file (or its cache)
compr	Indicates whether there should be compression with gzip.

Returns

Regular conventions (OK -> 0).

Definition at line 1724 of file sort.c.

4.100.3.8 AddCoef()

```
WORD AddCoef (
            PHEAD WORD ** ps1,
            WORD ** ps2 )
```

Adds the coefficients of the terms ∗ps1 and ∗ps2. The problem comes when there is not enough space for a new longer coefficient. First a local solution is tried. If this is not succesfull we need to move terms around. The possibility of a garbage collection should not be ignored, as avoiding this costs very much extra space which is nearly wasted otherwise.

If the return value is zero the terms cancelled.

The resulting term is left in ∗ps1.

Definition at line 1935 of file sort.c.

References GarbHand(), and NormalModulus().

Referenced by SplitMerge().

Here is the call graph for this function:

4.100.3.9 AddPoly()

```
WORD AddPoly (
            PHEAD WORD ** ps1,
            WORD ** ps2 )
```

Routine should be called when S->PolyWise != 0. It points then to the position of AR.PolyFun in both terms.

We add the contents of the arguments of the two polynomials. Special attention has to be given to special arguments. We have to reserve a space equal to the size of one term + the size of the argument of the other. The addition has to be done in this routine because not all objects are reentrant.

Newer addition (12-nov-2007). The PolyFun can have two arguments. In that case S->PolyFlag is 2 and we have to call the routine for adding rational polynomials. We have to be rather careful what happens with: The location of the output The order of the terms in the arguments At first we allow only univariate polynomials in the PolyFun. This restriction will be lifted a.s.a.p.

Parameters

ps1	A pointer to the postion of the first term
ps2	A pointer to the postion of the second term

Returns

If zero the terms cancel. Otherwise the new term is in ∗ps1.

Definition at line 2062 of file sort.c.

References AddArgs(), and GarbHand().

Referenced by SplitMerge().

Here is the call graph for this function:

4.100.3.10 AddArgs()

```
VOID AddArgs (
            PHEAD WORD * s1,
            WORD * s2,
            WORD * m )
```

Adds the arguments of two occurrences of the PolyFun.

Parameters

s1	Pointer to the first occurrence.
s2	Pointer to the second occurrence.
m	Pointer to where the answer should be.

Definition at line 2224 of file sort.c.

Referenced by AddPoly(), and MergePatches().

4.100.3.11 Compare1()

```
WORD Compare1 (
            PHEAD WORD * term1,
            WORD * term2,
            WORD level )
```

Compares two terms. The answer is: 0 equal (with exception of the coefficient if level == 0.) >0 term1 comes first. <0 term2 comes first. Some special precautions may be needed to keep the CompCoef routine from generating overflows, although this is very unlikely in subterms. This routine should not return an error condition.

Originally this routine was called Compare. With the treatment of special polynomials with terms that contain only symbols and the need for extreme speed for the polynomial routines we made a special compare routine and now we store the address of the current compare routine in AR.CompareRoutine and have a macro Compare which makes all existing code work properly and we can just replace the routine on a thread by thread basis (each thread has its own AR struct).

Parameters

term1	First input term
term2	Second input term
level	The sorting level (may influence on the result)

Returns

0 equal (with exception of the coefficient if level == 0.) >0 term1 comes first. <0 term2 comes first.

Definition at line 2509 of file sort.c.

References CompCoef().

Referenced by InFunction(), and StartVariables().

Here is the call graph for this function:

4.100.3.12 CompareSymbols()

```
int CompareSymbols (
            PHEAD WORD * term1,
            WORD * term2,
            WORD par )
```

Compares the terms, based on the value of AN.polysortflag. If term1 < term2 the return value is -1 If term1 > term2 the return value is 1 If term1 = term2 the return value is 0 The coefficients may differ. The terms contain only a single subterm of type SYMBOL. If AN.polysortflag = 0 it is a 'regular' compare. If AN.polysortflag = 1 the sum of the powers is more important par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in sort.c

Definition at line 2945 of file sort.c.

Referenced by InFunction(), and TestSub().

4.100.3.13 CompareHSymbols()

```
int CompareHSymbols (
            PHEAD WORD * term1,
            WORD * term2,
            WORD par )
```

Compares terms that can have only SYMBOL and HAAKJE subterms. If term1 < term2 the return value is -1 If term1 > term2 the return value is 1 If term1 = term2 the return value is 0 par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in sort.c

Definition at line 2988 of file sort.c.

4.100.3.14 ComPress()

```
LONG ComPress (
            WORD ** ss,
            LONG * n )
```

Gets a list of pointers to terms and compresses the terms. In n it collects the number of terms and the return value of the function is the space that is occupied.

We have to pay some special attention to the compression of terms with a PolyFun. This PolyFun should occur only straight before the coefficient, so we can use the same trick as for the coefficient to sabotage compression of this object (Replace in the history the function pointer by zero. This is safe, because terms that would be identical otherwise would have been added).

Parameters

ss	Array of pointers to terms to be compressed.
n	Number of pointers in ss.

Returns

Total number of words needed for the compressed result.

Definition at line 3041 of file sort.c.

Referenced by EndSort(), and StoreTerm().

4.100.3.15 SplitMerge()

```
LONG SplitMerge (
            PHEAD WORD ** Pointer,
            LONG number )
```

Algorithm by J.A.M.Vermaseren (31-7-1988)

Note that AN.SplitScratch and AN.InScratch are used also in GarbHand

Merge sort in memory. The input is an array of pointers. Sorting is done recursively by dividing the array in two equal parts and calling SplitMerge for each. When the parts are small enough we can do the compare and take the appropriate action. An addition is that we look for 'runs'. Sequences that are already ordered. This happens a lot when there is very little action in a module. This made FORM faster by a few percent.

Parameters

Pointer	The array of pointers to the terms to be sorted.
number	The number of pointers in Pointer.

The terms are supposed to be sitting in the small buffer and there is supposed to be an extension to this buffer for when there are two terms that should be added and the result takes more space than each of the original terms. The notation guarantees that the result never needs more space than the sum of the spaces of the original terms.

Definition at line 3207 of file sort.c.

Here is the call graph for this function:

4.100.3.16 GarbHand()

```
VOID GarbHand ( )
```

Garbage collection that takes place when the small extension is full and we need to place more terms there. When this is the case there are many holes in the small buffer and the whole can be compactified. The major complication

is the buffer for SplitMerge. There are to options for temporary memory: 1: find some buffer that has enough space (maybe in the large buffer). 2: allocate a buffer. Give it back afterwards of course. If the small extension is properly dimensioned this routine should be called very rarely. Most of the time it will be called when the polyfun or polyratfun is active.

Definition at line 3383 of file sort.c.

Referenced by AddCoef(), and AddPoly().

4.100.3.17 MergePatches()

```
WORD MergePatches (
            WORD par )
```

The general merge routine. Can be used for the large buffer and the file merging. The array S->Patches tells where the patches start S->pStop tells where they end (has to be computed first). The end of a 'line to be merged' is indicated by a zero. If the end is reached without running into a zero or a term runs over the boundary of a patch it is a file merging operation and a new piece from the file is read in.

Parameters

par	If par == 0 the sort is for file -> outputfile. If par == 1 the sort is for large buffer -> sortfile. If par == 2 the sort is for large buffer -> outputfile.

Definition at line 3498 of file sort.c.

References AddArgs(), FlushOut(), FiLe::handle, NormalModulus(), PutIn(), PutOut(), Sflush(), and StageSort().

Referenced by EndSort(), and StoreTerm().

Here is the call graph for this function:

4.100.3.18 StoreTerm()

```
WORD StoreTerm (
            PHEAD WORD * term )
```

The central routine to accept terms, store them and keep things at least partially sorted. A call to EndSort will then complete storing and sorting.

Parameters

term	The term to be stored

Returns

Regular return conventions (OK -> 0)

Definition at line 4246 of file sort.c.

4.100.3.19 StageSort()

```
VOID StageSort (
            FILEHANDLE * fout )
```

Prepares a stage 4 or higher sort. Stage 4 sorts occur when the sort file contains more patches than can be merged in one pass.

Definition at line 4364 of file sort.c.

References FiLe::handle.

Referenced by EndSort(), and MergePatches().

4.100.3.20 SortWild()

```
WORD SortWild (
            WORD * w,
            WORD nw )
```

Sorts the wildcard entries in the parameter w. Double entries are removed. Full space taken is nw words. Routine serves for the reading of wildcards in the compiler. The entries come in the format: (type,4,number,0) in which the zero is reserved for the future replacement of 'number'.

Parameters

w	buffer with wildcard entries.
nw	number of wildcard entries.

Returns

Normal conventions (OK -> 0)

Definition at line 4444 of file sort.c.

4.100.3.21 CleanUpSort()

```
void CleanUpSort (
            int num )
```

Partially or completely frees function sort buffers.

Definition at line 4536 of file sort.c.

    #[ Commentary :

    We use an array of SPECTATOR structs in AM.SpectatorFiles.
    When a spectator is removed this leaves a hole. This means that
    we cannot use AM.NumSpectatorFiles but always have to scan up to
    AM.SizeForSpectatorFiles which is the size of the array.
    An element is in use when it has a name. This is the name of the
    expression that is associated with it. There is also the number of
    the expression, but because the expressions are frequently renumbered
    at the end of a module, we always search for the spectators by name.
    The expression number is only valid in the current module.
    During execution we use the number of the spectator.

    The FILEHANDLE struct is borrowed from the structs for the scratch
    files, but we do not keep copies for all workers as with the scratch
    files. This brings some limitations (but saves much space). Basically
    the reading can only be done by one master or worker. And because
    we use the buffer both for writing and for reading we cannot read and
    write in the same module.

    Processor can see that an expression is to be filled with a spectator
    because we replace the compiler buffer number in the prototype by
    -specnum-1. Of course, after this filling has taken place we should
    make sure that in the next module there is a nonnegative number there.
    The input is then obtained from GetFromSpectator instead from GetTerm.
    This needed an extra argument in ThreadsProcessor. InParallelProcessor
    can figure it out by itself. ParFORM still needs to be treated for this.

    The writing is to a single buffer. Hence it needs a lock. It is possible
    to give all workers their own buffers (at great memory cost) and merge
    the results when needed. That would be friendlier on ParFORM. We ALWAYS
    assume that the order of the terms in the spectator file is random.

    In the first version there is no compression in the file. This could
    change in later versions because both the writing and the reading are
    purely sequential. Brackets are not possible.

    Currently, ParFORM allows use of spectators only in the sequential
    mode. The parallelization is switched off in modules containing
    ToSpectator or CopySpectator. Workers never create or access to
    spectator files. Their file handles are always -1. We leave the
    parallelization of modules with spectators for future work.

4.104.1 Detailed Description

This file contains the main program. It also deals with the very early stages of the startup of FORM and the final stages when the program attemps some cleanup. Here is the routine that analyses the command tail.

Definition in file startup.c.

4.104.2 Macro Definition Documentation

4.104.2.1 STRINGIFY

```
#define STRINGIFY(
              x ) STRINGIFY__(x)
```

Definition at line 50 of file startup.c.

4.104.2.2 STRINGIFY__

```
#define STRINGIFY__(
              x ) #x
```

Definition at line 51 of file startup.c.

4.104.2.3 FORMNAME

```
#define FORMNAME "FORM"
```

Definition at line 61 of file startup.c.

4.104.2.4 VERSIONSTR__

```
#define VERSIONSTR__ STRINGIFY(MAJORVERSION) "." STRINGIFY(MINORVERSION)
```

Definition at line 92 of file startup.c.

4.104.2.5 VERSIONSTR

```
#define VERSIONSTR FORMNAME " " VERSIONSTR__ " (" PRODUCTIONDATE ")"
```

Definition at line 94 of file startup.c.

4.104.2.6 TAKEPATH

```
#define TAKEPATH(
              x ) if(s[1]== '=' ){x=s+2;} else{x=*argv++;argc--;}
```

Definition at line 215 of file startup.c.

4.104.3 Function Documentation

4.104.3.1 DoTail()

```
int DoTail (
            int argc,
            UBYTE ** argv )
```

Definition at line 217 of file startup.c.

4.104.3.2 OpenInput()

```
int OpenInput ( )
```

Definition at line 480 of file startup.c.

4.104.3.3 ReserveTempFiles()

```
VOID ReserveTempFiles (
            int par )
```

Definition at line 593 of file startup.c.

4.104.3.4 StartVariables()

```
VOID StartVariables ( )
```

All functions (well, nearly all) are declared here.

Definition at line 828 of file startup.c.

References AddNtoC(), AddRHS(), Compare1(), inicbufs(), FuNcTiOn::name, PF_BroadcastNumber(), PutPreVar(), and FuNcTiOn::symmetric.

Here is the call graph for this function:

4.104.3.5 StartMore()

```
VOID StartMore ( )
```

Definition at line 1200 of file startup.c.

4.104.3.6 IniVars()

```
WORD IniVars ( )
```

Definition at line 1238 of file startup.c.

4.104.3.7 main()

```
int main (
            int argc,
            char ** argv )
```

Definition at line 1526 of file startup.c.

4.104.3.8 CleanUp()

```
VOID CleanUp (
            WORD par )
```

Definition at line 1619 of file startup.c.

4.104.3.9 Terminate()

```
VOID Terminate (
            int errorcode )
```

Definition at line 1696 of file startup.c.

4.104.3.10 PrintRunningTime()

```
VOID PrintRunningTime ( )
```

Definition at line 1777 of file startup.c.

4.104.3.11 GetRunningTime()

```
LONG GetRunningTime ( )
```

Definition at line 1818 of file startup.c.

4.104.4 Variable Documentation

4.104.4.1 emptystring

```
UBYTE* emptystring = (UBYTE *)"."
```

Definition at line 590 of file startup.c.

4.104.4.2 defaulttempfilename

```
UBYTE* defaulttempfilename = (UBYTE *)"xformxxx.str"
```

Definition at line 591 of file startup.c.

4.106.1 Detailed Description

Contains all functions that deal with store-files and the system independent save-files.

Definition in file store.c.

4.106.2 Macro Definition Documentation

4.106.2.1 SAVEREVISION

```
#define SAVEREVISION 0x02
```

Definition at line 3915 of file store.c.

4.106.3 Function Documentation

4.106.3.1 OpenTemp()

```
WORD OpenTemp ( )
```

Definition at line 48 of file store.c.

4.106.3.2 SeekScratch()

```
VOID SeekScratch (
            FILEHANDLE * fi,
            POSITION * pos )
```

Definition at line 64 of file store.c.

4.106.3.3 SetEndScratch()

```
VOID SetEndScratch (
            FILEHANDLE * f,
            POSITION * position )
```

Definition at line 75 of file store.c.

4.106.3.4 SetEndHScratch()

```
VOID SetEndHScratch (
            FILEHANDLE * f,
            POSITION * position )
```

Definition at line 89 of file store.c.

4.106.3.5 SetScratch()

```
VOID SetScratch (
            FILEHANDLE * f,
            POSITION * position )
```

Definition at line 115 of file store.c.

4.106.3.6 RevertScratch()

```
WORD RevertScratch ( )
```

Definition at line 190 of file store.c.

4.106.3.7 ResetScratch()

```
WORD ResetScratch ( )
```

Definition at line 235 of file store.c.

4.106.3.8 ReadFromScratch()

int ReadFromScratch (
            FILEHANDLE * fi,
            POSITION * pos,
            UBYTE * buffer,
            POSITION * length )
```

Definition at line 273 of file store.c.

4.106.3.9 AddToScratch()

```
int AddToScratch (
            FILEHANDLE * fi,
            POSITION * pos,
            UBYTE * buffer,
            POSITION * length,
            int withflush )
```

Definition at line 300 of file store.c.

4.106.3.10 CoSave()

```
int CoSave (
            UBYTE * inp )
```

Definition at line 363 of file store.c.

4.106.3.11 CoLoad()

```
int CoLoad (
            UBYTE * inp )
```

Definition at line 561 of file store.c.

4.106.3.12 DeleteStore()

```
WORD DeleteStore (
            WORD par )
```

Definition at line 761 of file store.c.

4.106.3.13 PutInStore()

```
WORD PutInStore (
            INDEXENTRY * ind,
            WORD num )
```

Definition at line 861 of file store.c.

4.106.3.14 GetTerm()

```
WORD GetTerm (
            PHEAD WORD * term )
```

Definition at line 980 of file store.c.

4.106.3.15 GetOneTerm()

```
WORD GetOneTerm (
            PHEAD WORD * term,
            FILEHANDLE * fi,
            POSITION * pos,
            int par )
```

Definition at line 1255 of file store.c.

4.106.3.16 GetMoreTerms()

```
WORD GetMoreTerms (
            WORD * term )
```

Definition at line 1412 of file store.c.

4.106.3.17 GetMoreFromMem()

```
WORD GetMoreFromMem (
            WORD * term,
            WORD ** tpoin )
```

Definition at line 1508 of file store.c.

4.106.3.18 GetFromStore()

```
WORD GetFromStore (
            WORD * to,
            POSITION * position,
            RENUMBER renumber,
            WORD * InCompState,
            WORD nexpr )
```

Definition at line 1615 of file store.c.

4.106.3.19 DetVars()

```
VOID DetVars (
            WORD * term,
            WORD par )
```

Definition at line 1814 of file store.c.

4.106.3.20 ToStorage()

```
WORD ToStorage (
            EXPRESSIONS e,
            POSITION * length )
```

Definition at line 2001 of file store.c.

4.106.3.21 NextFileIndex()

```
INDEXENTRY * NextFileIndex (
            POSITION * indexpos )
```

Definition at line 2237 of file store.c.

4.106.3.22 SetFileIndex()

```
WORD SetFileIndex ( )
```

Reads the next file index and puts it into AR.StoreData.Index. TODO

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 2300 of file store.c.

References WriteStoreHeader().

            WORD expr,
            POSITION * position,
            WORD mode )
```

Definition at line 2805 of file store.c.

4.106.3.28 CopyExpression()

```
int CopyExpression (
            FILEHANDLE * from,
            FILEHANDLE * to )
```

Definition at line 3262 of file store.c.

4.106.3.29 WriteStoreHeader()

```
WORD WriteStoreHeader (
            WORD handle )
```

Writes header with information about system architecture and FORM revision to an open store file.

Called by SetFileIndex().

Parameters

handle	specifies open file to which header will be written

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 3926 of file store.c.

References STOREHEADER::endianness, STOREHEADER::lenLONG, STOREHEADER::lenPOINTER, STOREHEADER::lenPOS, STOREHEADER::lenWORD, STOREHEADER::maxpower, STOREHEADER::sFun, STOREHEADER::sInd, STOREHEADER::sSym, STOREHEADER::sVec, and STOREHEADER::wildoffset.

Referenced by SetFileIndex().

4.106.3.30 ReadSaveHeader()

```
WORD ReadSaveHeader ( )
```

Reads the header in the save file and sets function pointers and flags according to the information found there. Must be called before any other ReadSave... function.

Currently works only for the exchange between 32bit and 64bit machines (WORD size must be 2 or 4 bytes)!

It is called by CoLoad().

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4019 of file store.c.

4.106.3.31 ReadSaveIndex()

```
WORD ReadSaveIndex (
            FILEINDEX * fileind )
```

Reads a FILEINDEX from the open save file specified by AO.SaveData.Handle. Translations for adjusting endianness and data sizes are done if necessary.

Depends on the assumption that sizeof(FILEINDEX) is the same everywhere. If FILEINDEX or INDEXENTRY change, then this functions has to be adjusted.

Called by CoLoad() and FindInIndex().

Parameters

fileind	contains the read FILEINDEX after succesful return. must point to allocated, big enough memory.

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4137 of file store.c.

References INFILEINDEX, FiLeInDeX::next, FiLeInDeX::number, and FuNcTiOn::number.

4.106.3.32 ReadSaveVariables()

```
WORD ReadSaveVariables (
            UBYTE * buffer,
            UBYTE * top,
            LONG * size,
            LONG * outsize,
            INDEXENTRY * ind,
            LONG * stage )
```

Reads the variables from the open file specified by AO.SaveData.Handle. It reads the ∗size bytes and writes them to the ∗buffer. It is called by PutInStore().

If translation is necessary, the data might shrink or grow in size, then ∗*size* is adjusted so that the reading and writing fits into the memory from the buffer to the top. The actual number of read bytes is returned in ∗*size*, the number of written bytes is returned in ∗*outsize*.

If the ∗size is smaller than the actual size of the variables, this function will be called several times and needs to remember the current position in the variable structure. The parameter *stage* does this job. When ReadSaveVariables() is called for the first time, this parameter should have the value -1.

The parameter *ind* is used to get the number of variables.

Parameters

buffer	read variables are written into this allocated memory
top	upper end of allocated memory
size	number of bytes to read. might return a smaller number of read bytes if translation was necessary
outsize	if translation has be done, outsize contains the number of written bytes
ind	pointer of INDEXENTRY for the current expression. read-only
stage	should be -1 for the first call, will be increased by ReadSaveVariables to memorize the position in the variable structure

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4323 of file store.c.

References InDeXeNtRy::nfunctions, InDeXeNtRy::nindices, InDeXeNtRy::nsymbols, InDeXeNtRy::nvectors, and FuNcTiOn::spec.

4.106.3.33 ReadSaveTerm32()

```
UBYTE * ReadSaveTerm32 (
            UBYTE * bin,
            UBYTE * binend,
            UBYTE ** bout,
            UBYTE * boutend,
            UBYTE * top,
            int terminbuf )
```

Reads a single term from the given buffer at *bin* and write the translated term back to this buffer at *bout*.

ReadSaveTerm32() is currently the only instantiation of a ReadSaveTerm-function. It only deals with data that already has the correct endianness and that is resized to 32bit words but without being renumbered or translated in any other way. It uses the compress buffer AR.CompressBuffer.

The function is reentrant in order to cope with nested function arguments. It is called by ReadSaveExpression() and itself.

The *return value* indicates the position in the input buffer up to which the data has already been successfully processed. The parameter *bout* returns the corresponding position in the output buffer.

Parameters

bin	start of the input buffer
binend	end of the input buffer
bout	as input points to the beginning of the output buffer, as output points behind the already translated data in the output buffer
boutend	end of already decompressed data in output buffer
top	end of output buffer
terminbuf	flag whether decompressed data is already in the output buffer. used in recursive calls

Returns

pointer to the next unprocessed data in the input buffer

Definition at line 4683 of file store.c.

References ReadSaveTerm32().

Referenced by ReadSaveExpression(), and ReadSaveTerm32().

Here is the call graph for this function:

4.106.3.34 ReadSaveExpression()

```
WORD ReadSaveExpression (
            UBYTE * buffer,
            UBYTE * top,
            LONG * size,
            LONG * outsize )
```

Reads an expression from the open file specified by AO.SaveData.Handle. The endianness flip and a resizing without renumbering is done in this function. Thereafter the buffer consists of chunks with a uniform maximal word size (32bit at the moment). The actual renumbering is then done by calling the function ReadSaveTerm32(). The result is returned in *buffer*.

If the translation at some point doesn't fit into the buffer anymore, the function returns and must be called again. In any case *size* returns the number of successfully read bytes, *outsize* returns the number of successfully written bytes, and the file will be positioned at the next byte after the successfully read data.

It is called by PutInStore().

Parameters

buffer	output buffer, holds the (translated) expression
top	end of buffer
size	number of read bytes
outsize	number of written bytes

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 5092 of file store.c.

References ReadSaveTerm32().

Here is the call graph for this function:

/*
        #] FindInIndex :
        #[ GetTable :

        Locates stored files and constructs the renumbering tables.
        They are allocated in the WorkSpace.
        First the expression data are located. The Index is treated
        as a circularly linked buffer which is paged forwardly.
        If the indexentry is located (in ind) the two renumber tables
        have to be constructed.
        Finally the prototype has to be put in the proper buffer, so
        that wildcards can be passed. There should be a test with
        an already existing prototype that is constructed by the
        pattern matcher. This has not been put in yet.

        There is a problem with the parallel processing.
        Feeding in the variables that were erased by a .store could in
        principle happen in different orders (ParFORM) or simultaneously
        (TFORM). The proper resolution is to have the compiler call GetTable
        when a stored expression is encountered.

        This has been mended in development of TFORM by reading the
        symbol tables during compilation. See the call to GetTable
        in the CodeGenerator.

        Next is the problem of FindInIndex which writes in AR.StoreData
        Copying this is expensive!

        This Doesn't work well for TFORM yet.!!!!!!!!
        e[x1,x2] versus e[x2,x1] messes up.
        For the rest is the reloading during execution not thread safe.

        The parameter mode tells whether we should worry about arguments
        of a stored expression.

4.108.1 Detailed Description

Contains definitions for global structs.

!!!CAUTION!!! Changes in this file will most likely have consequences for the recovery mechanism (see checkpoint.c). You need to care for the code in checkpoint.c as well and modify the code there accordingly!

The marker [D] is used in comments in this file to mark pointers to which dynamically allocated memory is assigned by a call to malloc() during runtime (in contrast to pointers that point into already allocated memory). This information is especially helpful if one needs to know which pointers need to be freed (cf. checkpoint.c).

Definition in file structs.h.

4.108.2 Macro Definition Documentation

4.108.2.1 INFILEINDEX

```
#define INFILEINDEX ((512-2*sizeof(POSITION))/sizeof(INDEXENTRY))
```

Maximum number of entries (struct InDeXeNtRy) in a file index (struct FiLeInDeX). Number is calculated such that the size of a file index is no more than 512 bytes.

Definition at line 118 of file structs.h.

4.108.2.2 EMPTYININDEX

```
#define EMPTYININDEX (512-2*sizeof(POSITION)-INFILEINDEX*sizeof(INDEXENTRY))
```

Number of empty filling bytes for a file index (struct FiLeInDeX). It is calculated such that the size of a file index is always 512 bytes.

Definition at line 123 of file structs.h.

4.108.3 Typedef Documentation

4.108.3.1 INDEXENTRY

```
typedef struct InDeXeNtRy INDEXENTRY
```

Defines the structure of an entry in a file index (see struct FiLeInDeX).

It represents one expression in the file.

4.108.3.2 FILEINDEX

```
typedef struct FiLeInDeX FILEINDEX
```

Defines the structure of a file index in store-files and save-files.

It contains several entries (see struct InDeXeNtRy) up to a maximum of INFILEINDEX.

The variable number has been made of type POSITION to avoid padding problems with some types of computers/↩ OS and keep system independence of the .sav files.

This struct is always 512 bytes long.

4.108.3.3 VARRENUM

```
typedef struct VaRrEnUm VARRENUM
```

Contains the pointers to an array in which a binary search will be performed.

4.108.3.4 RENUMBER

```
typedef struct ReNuMbEr * RENUMBER
```

Only symb.lo gets dynamically allocated. All other pointers points into this memory.

4.108.3.5 NAMENODE

```
typedef struct NaMeNode NAMENODE
```

The names of variables are kept in an array. Elements of type NAMENODE define a tree (that is kept balanced) that make it easy and fast to look for variables. See also NAMETREE.

4.108.3.6 NAMETREE

```
typedef struct NaMeTree NAMETREE
```

A struct of type NAMETREE controls a complete (balanced) tree of names for the compiler. The compiler maintains several of such trees and the system has been set up in such a way that one could define more of them if we ever want to work with local name spaces.

4.108.3.7 COMPTREE

```
typedef struct tree COMPTREE
```

The subexpressions in the compiler are kept track of in a (balanced) tree to reduce the need for subexpressions and hence save much space in large rhs expressions (like when we have xxxxxxx occurrences of objects like f(x+1,x+1) in which each x+1 becomes a subexpression. The struct that controls this tree is COMPTREE.

4.108.3.8 TABLES

```
typedef struct TaBlEs * TABLES
```

buffers, mm, flags, and prototype are always dynamically allocated, tablepointers only if needed (=0 if unallocated), boomlijst and argtail only for sparse tables.

Allocation is done for both the normal and the stub instance (spare), except for prototype and argtail which share memory.

4.108.3.9 FUNCTIONS

```
typedef struct FuNcTiOn * FUNCTIONS
```

Contains all information about a function. Also used for tables. It is used in the LIST elements of AC.

4.108.3.10 FILEHANDLE

```
typedef struct FiLe FILEHANDLE
```

The type FILEHANDLE is the struct that controls all relevant information of a file, whether it is open or not. The file may even not yet exist. There is a system of caches (PObuffer) and as long as the information to be written still fits inside the cache the file may never be created. There are variables that can store information about different types of files, like scratch files or sort files. Depending on what is available in the system we may also have information about gzip compression (currently sort file only) or locks (TFORM).

4.108.3.11 STREAM

```
typedef struct StreaM STREAM
```

Input is read from 'streams' which are represented by objects of type STREAM. A stream can be a file, a do-loop, a procedure, the string value of a preprocessor variable ..... When a new stream is opened we have to keep information about where to fall back in the parent stream to allow this to happen even in the middle of reading names etc as would be the case with a`i'b

4.108.3.12 TRACES

```
typedef struct TrAcEs TRACES
```

The struct TRACES keeps track of the progress during the expansion of a 4-dimensional trace. Each time a term gets generated the expansion tree continues in the next statement. When it returns it has to know where to continue. The 4-dimensional traces are more complicated than the n-dimensional traces (see TRACEN) because of the extra tricks that can be used. They are responsible for the shorter final expressions.

4.108.3.13 TRACEN

```
typedef struct TrAcEn * TRACEN
```

The struct TRACEN keeps track of the progress during the expansion of a 4-dimensional trace. Each time a term gets generated the expansion tree continues in the next statement. When it returns it has to know where to continue.

4.108.3.14 PREVAR

```
typedef struct pReVaR PREVAR
```

An element of the type PREVAR is needed for each preprocessor variable.

4.108.3.15 DOLOOP

```
typedef struct DoLoOp DOLOOP
```

Each preprocessor do loop has a struct of type DOLOOP to keep track of all relevant parameters like where the beginning of the loop is, what the boundaries, increment and value of the loop parameter are, etc. Also we keep the whole loop inside a buffer of type PRELOAD

4.108.3.16 set_of_char

```
typedef struct bit_field set_of_char[32]
```

Used in set_in, set_set, set_del and set_sub.

Definition at line 890 of file structs.h.

4.108.3.17 one_byte

```
typedef struct bit_field* one_byte
```

Used in set_in, set_set, set_del and set_sub.

Definition at line 896 of file structs.h.

4.108.3.18 CBUF

```
typedef struct CbUf CBUF
```

The CBUF struct is used by the compiler. It is a compiler buffer of which since version 3.0 there can be many.

4.108.3.19 CHANNEL

```
typedef struct ChAnNeL CHANNEL
```

When we read input from text files we have to remember not only their handle but also their name. This is needed for error messages. Hence we call such a file a channel and reserve a struct of type CHANNEL to allow to lay this link.

4.108.3.20 NESTING

```
typedef struct NeStInG * NESTING
```

The NESTING struct is used when we enter the argument of functions and there is the possibility that we have to change something there. Because functions can be nested we have to keep track of all levels of functions in case we have to move the outer layers to make room for a larger function argument.

4.108.3.21 STORECACHE

```
typedef struct StOrEcAcHe * STORECACHE
```

The struct of type STORECACHE is used by a caching system for reading terms from stored expressions. Each thread should have its own system of caches.

4.108.3.22 PERM

```
typedef struct PeRmUtE PERM
```

The struct PERM is used to generate all permutations when the pattern matcher has to try to match (anti)symmetric functions.

4.108.3.23 PERMP

```
typedef struct PeRmUtEp PERMP
```

Like struct PERM but works with pointers.

4.108.3.24 DISTRIBUTE

```
typedef struct DiStRiBuTe DISTRIBUTE
```

The struct DISTRIBUTE is used to help the pattern matcher when matching antisymmetric tensors.

4.108.3.25 PARTI

```
typedef struct PaRtI PARTI
```

The struct PARTI is used to help determining whether a partition_ function can be replaced.

4.108.3.26 SORTING

```
typedef struct sOrT SORTING
```

The struct SORTING is used to control a sort operation. It includes a small and a large buffer and arrays for keeping track of various stages of the (merge) sorts. Each sort level has its own struct and different levels can have different sizes for its arrays. Also different threads have their own set of SORTING structs.

4.108.3.27 ALLGLOBALS

```
typedef struct AllGlobals ALLGLOBALS
```

Without pthreads (FORM) the ALLGLOBALS struct has all the global variables

4.108.3.28 WCN

```
typedef WORD(* WCN) ()
```

Definition at line 2423 of file structs.h.

4.108.3.29 WCN2

```
typedef WORD(* WCN2) ()
```

Definition at line 2424 of file structs.h.

4.108.3.30 FIXEDGLOBALS

```
typedef struct FixedGlobals FIXEDGLOBALS
```

The FIXEDGLOBALS struct is an anachronism. It started as the struct with global variables that needed initialization. It contains the elements Operation and OperaFind which define a very early way of automatically jumping to the proper operation. We find the results of it in parts of the file opera.c Later operations were treated differently in a more transparent way. We never changed the existing code. The most important part is currently the cTable which is used intensively in the compiler.

4.110.1 Detailed Description

The routines that deal with the pattern matching of functions with symmetric properties.

Definition in file symmetr.c.

4.110.2 Function Documentation

4.110.2.1 MatchE()

```
WORD MatchE (
            PHEAD WORD * pattern,
            WORD * fun,
            WORD * inter,
            WORD par )
```

Definition at line 56 of file symmetr.c.

4.110.2.2 Permute()

```
WORD Permute (
            PERM * perm,
            WORD first )
```

Definition at line 443 of file symmetr.c.

4.110.2.3 PermuteP()

```
WORD PermuteP (
            PERMP * perm,
            WORD first )
```

Definition at line 477 of file symmetr.c.

4.110.2.4 Distribute()

```
WORD Distribute (
            DISTRIBUTE * d,
            WORD first )
```

Definition at line 509 of file symmetr.c.

4.110.2.5 MatchCy()

```
int MatchCy (
            PHEAD WORD * pattern,
            WORD * fun,
            WORD * inter,
            WORD par )
```

Definition at line 570 of file symmetr.c.

4.110.2.6 FunMatchCy()

```
int FunMatchCy (
            PHEAD WORD * pattern,
            WORD * fun,
            WORD * inter,
            WORD par )
```

Definition at line 1066 of file symmetr.c.

4.110.2.7 FunMatchSy()

```
int FunMatchSy (
            PHEAD WORD * pattern,
            WORD * fun,
            WORD * inter,
            WORD par )
```

Definition at line 1524 of file symmetr.c.

4.110.2.8 MatchArgument()

```
int MatchArgument (
            PHEAD WORD * arg,
            WORD * pat )
```

Definition at line 2051 of file symmetr.c.

    #] Includes :
    #[ MatchE :                 WORD MatchE(pattern,fun,inter,par)

        Matches symmetric and antisymmetric tensors.
        Pattern and fun point at a tensor.
        Problem is the wildcarding and all its possible permutations.
        This routine loops over all of them and calls for each
        possible wildcarding the recursion in ScanFunctions.
        Note that this can be very costly.

        Originally this routine did only Levi Civita tensors and hence
        it dealt only with commuting objects.
        Because of the backtracking we cannot fall back to the calling
        ScanFunctions routine and check the sequence of functions when
        non-commuting objects are involved.

/*
    Now there are only free wildcards left.
    Possibly the assigned values ate too many vectors.
    The rest has to be done the 'hard way' via permutations.
    This is too bad when there are 10 indices.
    This could cause 10! tries.
    We try to avoid the worst case by using a very special
    (somewhat slow) permutation routine that has as its worst
    cases some rather unlikely configurations, rather than some
    common ones (as would have been the case with the conventional
    permuation routine).
        assume:
        vvvvvvvvvvvvvvvvvvvv     (tvfix in tfixvec and tifix in tfixind)
        VVVVVVVVVVVVVVVVVVVV     (vwc in wcvec and iwc in wcind)
    Note: all further assignments are possible at this point!
    Strategy:
        permute v
        permute i
        loop over the ordered distribution of the leftover v's
        through the i's.

    #[ Permute :                WORD Permute(perm,first)

        Special permutation function.
        Works recursively.
        The aim is to cycle through in as fast a way as possible,
        to take care that each object hits the various positions
        already early in the game.

        Start at two: -> cycle of two
        then three -> cycle of three
        etc;
        The innermost cycle is the longest. This is the opposite
        of the usual way of generating permutations and it is
        certainly not the fastest one. It allows for the fastest
        hit in the assignment of wildcards though.

4.112.1 Detailed Description

Contains all functions that deal with the table bases on the 'FORM level' The low level databse routines are in minos.c

Definition in file tables.c.

4.112.2 Function Documentation

4.112.2.1 ClearTableTree()

```
void ClearTableTree (
            TABLES T )
```

Definition at line 71 of file tables.c.

4.112.2.2 InsTableTree()

```
int InsTableTree (
            TABLES T,
            WORD * tp )
```

Definition at line 102 of file tables.c.

4.112.2.3 RedoTableTree()

```
void RedoTableTree (
            TABLES T,
            int newsize )
```

Definition at line 263 of file tables.c.

4.112.2.4 FindTableTree()

```
int FindTableTree (
            TABLES T,
            WORD * tp,
            int inc )
```

Definition at line 288 of file tables.c.

4.112.2.5 DoTableExpansion()

```
WORD DoTableExpansion (
            WORD * term,
            WORD level )
```

Definition at line 326 of file tables.c.

4.112.2.6 CoTableBase()

```
int CoTableBase (
            UBYTE * s )
```

Definition at line 575 of file tables.c.

4.112.2.7 FlipTable()

```
int FlipTable (
            FUNCTIONS f,
            int type )
```

Definition at line 619 of file tables.c.

4.112.2.8 SpareTable()

```
int SpareTable (
            TABLES TT )
```

Definition at line 642 of file tables.c.

4.112.2.9 FindTB()

```
DBASE * FindTB (
            UBYTE * name )
```

Definition at line 682 of file tables.c.

4.112.2.10 CoTBcreate()

```
int CoTBcreate (
            UBYTE * s )
```

Definition at line 704 of file tables.c.

4.112.2.11 CoTBopen()

```
int CoTBopen (
            UBYTE * s )
```

Definition at line 720 of file tables.c.

4.112.2.12 CoTBaddto()

```
int CoTBaddto (
            UBYTE * s )
```

Definition at line 738 of file tables.c.

4.112.2.13 CoTBenter()

```
int CoTBenter (
            UBYTE * s )
```

Definition at line 906 of file tables.c.

4.112.2.14 CoTestUse()

```
int CoTestUse (
            UBYTE * s )
```

Definition at line 1064 of file tables.c.

4.112.2.15 CheckTableDeclarations()

```
int CheckTableDeclarations (
            DBASE * d )
```

Definition at line 1109 of file tables.c.

4.112.2.16 CoTBload()

```
int CoTBload (
            UBYTE * ss )
```

Definition at line 1178 of file tables.c.

4.112.2.17 TestUse()

```
WORD TestUse (
            WORD * term,
            WORD level )
```

Definition at line 1334 of file tables.c.

4.112.2.18 CoTBaudit()

```
int CoTBaudit (
            UBYTE * s )
```

Definition at line 1393 of file tables.c.

4.112.2.19 CoTBon()

```
int CoTBon (
            UBYTE * s )
```

Definition at line 1433 of file tables.c.

4.112.2.20 CoTBoff()

```
int CoTBoff (
            UBYTE * s )
```

Definition at line 1464 of file tables.c.

4.112.2.21 CoTBcleanup()

```
int CoTBcleanup (
            UBYTE * s )
```

Definition at line 1495 of file tables.c.

4.112.2.22 CoTBreplace()

```
int CoTBreplace (
            UBYTE * s )
```

Definition at line 1507 of file tables.c.

4.112.2.23 CoTBuse()

```
int CoTBuse (
            UBYTE * s )
```

Definition at line 1522 of file tables.c.

4.112.2.24 CoApply()

```
int CoApply (
            UBYTE * s )
```

Definition at line 1713 of file tables.c.

4.112.2.25 CoTBhelp()

```
int CoTBhelp (
            UBYTE * s )
```

Definition at line 1800 of file tables.c.

4.112.2.26 ReWorkT()

```
VOID ReWorkT (
            WORD * term,
            WORD * funs,
            WORD numfuns )
```

Definition at line 1816 of file tables.c.

4.112.2.27 Apply()

```
WORD Apply (
            WORD * term,
            WORD level )
```

Definition at line 1897 of file tables.c.

4.112.2.28 ApplyExec()

```
int ApplyExec (
            WORD * term,
            int maxtogo,
            WORD level )
```

Definition at line 1956 of file tables.c.

4.112.2.29 ApplyReset()

```
WORD ApplyReset (
            WORD level )
```

Definition at line 2173 of file tables.c.

4.112.2.30 TableReset()

```
WORD TableReset ( )
```

Definition at line 2209 of file tables.c.

4.112.2.31 ReleaseTB()

```
int ReleaseTB ( )
```

Definition at line 2236 of file tables.c.

4.112.3 Variable Documentation

4.112.3.1 helptb

```
char* helptb[]

/*
    #[ Includes :

    File contains the routines for the tree structure of sparse tables
    We insert elements by
    InsTableTree(T,tp) with T the TABLES element and tp the pointer
        to the indices.
    We look for elements with
    FindTableTree(T,tp,inc) with T the TABLES element, tp the pointer to the
        indices or the function arguments and inc tells which of these options.
    The tree is cleared with ClearTableTree(T) and we rebuild the tree
    after a .store in which we lost a part of the table with
    RedoTableTree(T,newsize)

    In T->tablepointers we have the lists of indices for each element.
    Additionally for each element there is an extension. There are
    TABLEEXTENSION WORDs reserved for that. The old system had two words
    One for the element in the rhs of the compile buffer and one for
    an additional rhs in case the original would be overwritten by a new
    definition, but the old was fixed by .global and hence it should be possible
    to restore it.
    New use (new = 24-sep-2001)
        rhs1,numCompBuffer1,rhs2,numCompBuffer2,usage
    Hence TABLEEXTENSION will be 5. Note that for 64 bits the use of the
    compiler buffer is overdoing it a bit, but it would be too complicated
    to try to give it special code.

/*
    #] InsTableTree :
    #[ RedoTableTree :

    To be used when a sparse table is trimmed due to a .store
    We rebuild the tree. In the future one could try to become faster
    at the cost of quite some complexity.
    We need to keep the first 'size' elements in the boomlijst.
    Kill all others and reconstruct the tree with the original ordering.
    This is very complicated! Because .store will either keep the whole
    table or remove the whole table we should not come here often.
    Hence we choose the slow solution for now.
```

```

```
        Open "File.tbl";                  Open for R/W
        Create "File.tbl";                Create for write
        Load "File.tbl", tablename;       Loads stubs of table
        Load "File.tbl";                  Loads stubs of all tables
        Enter "File.tbl", tablename;      Loads whole table
        Enter "File.tbl";                 Loads all tables
        Audit "File.tbl", options;        Print list of contents
        Replace "File.tbl", tablename;    Saves a table (with overwrite)
        Replace "File.tbl", table element; Saves a table element   „
        Cleanup "File.tbl";               Makes tables contingent
        AddTo "File.tbl" tablename;       Add if not yet there.
        AddTo "File.tbl" table element;   Add if not yet there.
        Delete "File.tbl" tablename;
        Delete "File.tbl" table element;

        On/Off substitute;
        On/Off compress "File.tbl";
    id tbl_(f?,?a) = f(?a);
    When a tbl_ is used, automatically the corresponding element is compiled
    at the start of the next module.
    if TB,On,substitue [tablename], use of table RHS (if loaded)
    if TB,Off,substitue [tablename], use of tbl_(table,...);

    Still needed: Something like OverLoad to allow loading parts of a table
    from more than one file. Date stamps needed? In that case we need a touch
    command as well.

    If we put all our diagrams inside, we have to go outside the concept
    of tables.

/*
    #] Apply :
    #[ ApplyExec :

    Replaces occurrences of tbl_(table,indices,pattern) by the proper
    rhs of table(indices,pattern). It does this up to maxtogo times
    in the given term. It starts with the occurrences inside the
    arguments of functions. If necessary it finishes at groundlevel.
    An infite number of tries is indicates by maxtogo = 2^15-1 or 2^31-1.
    The occurrences are replaced by subexpressions. This allows TestSub
    to finish the job properly.

    The main trick here is T = T->spare which turns to the proper rhs.

    The return value is the number of substitutions that can still be made
    based on maxtogo. Hence, if the returnvalue is different from maxtogo
    there was a substitution.

4.114 threads.c File Reference

4.114.1 Detailed Description

Routines for the interface of FORM with the pthreads library

This is the main part of the parallelization of TFORM. It is important to also look in the files structs.h and variable.h because the treatment of the A and B structs is essential (these structs are used by means of the macros AM, AP, AC, AS, AR, AT, AN, AO and AX). Also the definitions and use of the macros BHEAD and PHEAD should be looked up.

The sources are set up in such a way that if WITHPTHREADS isn't defined there is no trace of pthread parallelization. The reason is that TFORM is far more memory hungry than sequential FORM.

Special attention should also go to the locks. The proper use of the locks is essential and determines whether TFORM can work at all. We use the LOCK/UNLOCK macros which are empty in the case of sequential FORM These locks are at many places in the source files when workers can interfere with each others data or with the data of the master.

Definition in file threads.c.

00054
00055     The sortbot additions are from 17-may-2007 and after. They consitute
00056     an attempt to make the final merge sorting faster for the master.
00057     This way the master has only one compare per term.
00058     It does add some complexity, but the final merge routine (MasterMerge)
00059     is much simpler for the sortbots. On the other hand the original merging is
00060     for a large part a copy of the MergePatches routine in sort.c and hence
00061     even though complex the bad part has been thoroughly debugged.

/*
            12-jun-2007 JV:
    For the timing one has to know a few things:
    The POSIX standard is that there is only a single process ID and that
    getrusage returns the time of all the threads together.
    Under Linux there are two methods though: The older LinuxThreads and NPTL.
    LinuxThreads gives each thread its own process id. This makes that we
    can time the threads with getrusage, and hence this was done. Under NPTL
    this has been 'corrected' and suddenly getruage doesn't work anymore the
```

```
    way it used to. Now we need
        clock_gettime(CLOCK_THREAD_CPUTIME_ID,&timing)
    which is declared in <time.h> and we need -lrt extra in the link statement.
    (this is at least the case on blade02 at DESY-Zeuthen).
    See also the code in tools.c at the routine Timer.
    We may still have to include more stuff there.

```

```
                When a thread has to do a complete (not too big) expression.
                The number of the expression to be done is in AR.exprtodo.
                The code is mostly taken from Processor. The only difference
                is with what to do with the output.
                The output should go to the scratch buffer of the worker
                (which is free at the right moment). If this buffer is too
                small we have a problem. We could write to file or give the
                master what we have and from now on the master has to collect
                pieces until things are complete.
                Note: this assumes that the expressions don't keep their order.
                If they have to keep their order, don't use this feature.

            #] DOONEEXPRESSION :
            #[ DOBRACKETS :

                In case we have a bracket index we can have the worker treat
                one or more of the entries in the bracket index.
                The advantage is that identical terms will meet each other
                sooner in the sorting and hence fewer compares will be needed.
                Also this way the master doesn't need to fill the buckets.
                The main problem is the load balancing which can become very
                bad when there is a long tail without things outside the bracket.

                We get sent:

4.116.1 Detailed Description

The tokenizer. This is a part of the compiler that does an intermediate type of translation. It does look up the names etc and can do a number of optimizations. The resulting output is a stream of bytes which can be processed by the code generator (in the file compiler.c)

Definition in file token.c.

4.116.2 Macro Definition Documentation

4.116.2.1 CHECKPOLY

```
#define CHECKPOLY {if(polyflag)MesPrint("&Illegal use of polynomial function"); polyflag = 0;
}
```

Definition at line 56 of file token.c.

4.116.3 Function Documentation

4.116.3.1 tokenize()

```
int tokenize (
            UBYTE * in,
            WORD leftright )
```

Definition at line 58 of file token.c.

4.116.3.2 WriteTokens()

```
void WriteTokens (
            SBYTE * in )
```

Definition at line 592 of file token.c.

4.116.3.3 simp1token()

```
int simp1token (
            SBYTE * s )
```

Definition at line 640 of file token.c.

4.116.3.4 simpwtoken()

```
int simpwtoken (
            SBYTE * s )
```

Definition at line 729 of file token.c.

4.116.3.5 simp2token()

```
int simp2token (
            SBYTE * s )
```

Definition at line 883 of file token.c.

4.116.3.6 simp3atoken()

```
int simp3atoken (
            SBYTE * s,
            int mode )
```

Definition at line 1127 of file token.c.

4.116.3.7 simp3btoken()

```
int simp3btoken (
            SBYTE * s,
            int mode )
```

Definition at line 1350 of file token.c.

4.116.3.8 simp4token()

```
int simp4token (
            SBYTE * s )
```

Definition at line 1726 of file token.c.

4.116.3.9 simp5token()

```
int simp5token (
            SBYTE * s,
            int mode )
```

Definition at line 1883 of file token.c.

4.116.3.10 simp6token()

```
int simp6token (
            SBYTE * tokens,
            int mode )
```

Definition at line 1929 of file token.c.

4.116.4 Variable Documentation

4.116.4.1 ttypes

```
char* ttypes[]
```

Initial value:

```
= { "\n", "S", "I", "V", "F", "set", "E", "dotp", "#",
   "sub", "d_", "$", "dub", "(", ")", "?", "??", ".", "[", "]",
   ",", "((", ))", "*", "/", "^", "+", "-", "!", "end", "{{", "}}",
   "N_?", "conj", "()", "#d", "^d", "_", "snum"  }
```

Definition at line 587 of file token.c.

        #[ simpwtoken :

        Only to be called in the LHS.
        Hunts down the wildcards and writes them to the wildcardbuffer.
        Next it causes the ProtoType to be constructed.
        All wildcards are simplified into the trailing TWILDCARD,
        because the specifics are stored in the prototype.
        These specifics also include the transfer of wildcard values
        to $variables.

        Types of wildcards:
        a?, a?set, a?!set, a?set[i], A?set1?set2, ?a
        After this we can strip the set information.
        We still need the ? because of the wildcarding offset in code generation

4.118.1 Detailed Description

Low level routines for many types of task. There are routines for manipulating the input system (streams and files) routines for string manipulation, the memory allocation interface, and the clock. The last is the most sensitive to ports. In the past nearly every port to another OS or computer gave trouble. Nowadays it is slightly better but the poor POSIX compliance of LINUX again gave problems for the multithreaded version.

4.118.2 Macro Definition Documentation

4.118.2.1 FILLVALUE

```
#define FILLVALUE 0
```

Definition at line 49 of file tools.c.

4.118.2.2 TERMMEMSTARTNUM

```
#define TERMMEMSTARTNUM 16
```

Provides memory for one term (or one small polynomial) This means that the memory is limited to a buffer of size AM.MaxTer plus a few extra words. In parallel versions, each worker has its own memory pool.

The way we use the memory is by: term = TermMalloc(BHEAD0); and later we free it by TermFree(BHEAD term);

Layout: We have a list of available pointers to buffers: AT.TermMemHeap Its size is AT.TermMemMax We take from the top (indicated by AT.TermMemTop). When we run out of buffers we assign new ones (doubling the amount) and we have to extend the AT.TermMemHeap array. Important: There is no checking that the returned memory is legal, ie is memory that was handed out earlier.

Definition at line 2460 of file tools.c.

4.118.2.3 TERMEXTRAWORDS

```
#define TERMEXTRAWORDS 10
```

Definition at line 2461 of file tools.c.

4.118.2.4 NUMBERMEMSTARTNUM

```
#define NUMBERMEMSTARTNUM 16
```

Provides memory for one Long number This means that the memory is limited to a buffer of size AM.MaxTal In parallel versions, each worker has its own memory pool.

The way we use the memory is by: num = NumberMalloc(BHEAD0); Number = AT.NumberMemHeap[num]; and later we free it by NumberFree(BHEAD num);

Layout: We have a list of available pointers to buffers: AT.NumberMemHeap Its size is AT.NumberMemMax We take from the top (indicated by AT.NumberMemTop). When we run out of buffers we assign new ones (doubling the amount) and we have to extend the AT.NumberMemHeap array. Important: There is no checking on the returned memory!!!!

Definition at line 2560 of file tools.c.

4.118.2.5 NUMBEREXTRAWORDS

```
#define NUMBEREXTRAWORDS 10L
```

Definition at line 2561 of file tools.c.

4.118.2.6 DODOUBLE

```
#define DODOUBLE(
               x )
```

Value:

```
{ x *s, *t, *u; if ( *start ) { \
oldsize = *(x **)stop - *(x **)start; newsize = 2*oldsize; \
t = u = (x *)Malloc1(newsize*sizeof(x),text); s = *(x **)start; \
for ( i = 0; i < oldsize; i++ ) *t++ = *s++; M_free(*start,"double"); } \
else { newsize = 100; u = (x *)Malloc1(newsize*sizeof(x),text); } \
*start = (void *)u; *stop = (void *)(u+newsize); }
```

Definition at line 2883 of file tools.c.

4.118.2.7 DOEXPAND

```
#define DOEXPAND(
               x )
```

Value:

```
{ x *newbuffer, *t, *m;                                \
t = newbuffer = (x *)Malloc1((newsize+2)*type,"ExpandBuffer");      \
if ( *buffer ) { m = (x *)*buffer; i = *oldsize;                    \
    while ( --i >= 0 ) *t++ = *m++; M_free(*buffer,"ExpandBuffer"); \
} *buffer = newbuffer; *oldsize = newsize; }

```

Definition at line 2719 of file tools.c.

4.118.3.70 FromVarList()

```
VOID * FromVarList (
            LIST * L )
```

Definition at line 2748 of file tools.c.

4.118.3.71 DoubleList()

```
int DoubleList (
            VOID *** lijst,
            int * oldsize,
            int objectsize,
            char * nameoftype )
```

Definition at line 2790 of file tools.c.

4.118.3.72 DoubleLList()

```
int DoubleLList (
            VOID *** lijst,
            LONG * oldsize,
            int objectsize,
            char * nameoftype )
```

Definition at line 2842 of file tools.c.

4.118.3.73 DoubleBuffer()

```
void DoubleBuffer (
            void ** start,
            void ** stop,
            int size,
            char * text )
```

Definition at line 2890 of file tools.c.

4.118.3.74 ExpandBuffer()

```
void ExpandBuffer (
            void ** buffer,
            LONG * oldsize,
            int type )
```

Definition at line 2915 of file tools.c.

4.118.3.75 iexp()

```
LONG iexp (
            LONG x,
            int p )
```

Definition at line 2939 of file tools.c.

4.118.3.76 ToGeneral()

```
void ToGeneral (
            WORD * r,
            WORD * m,
            WORD par )
```

Definition at line 2969 of file tools.c.

4.118.3.77 ToFast()

```
int ToFast (
            WORD * r,
            WORD * m )
```

Definition at line 3009 of file tools.c.

4.118.3.78 ToPolyFunGeneral()

```
WORD ToPolyFunGeneral (
            PHEAD WORD * term )
```

Definition at line 3062 of file tools.c.

4.118.3.79 IsLikeVector()

```
int IsLikeVector (
            WORD * arg )
```

Definition at line 3137 of file tools.c.

4.118.3.80 AreArgsEqual()

```
int AreArgsEqual (
            WORD * arg1,
            WORD * arg2 )
```

Definition at line 3165 of file tools.c.

4.118.3.81 CompareArgs()

```
int CompareArgs (
            WORD * arg1,
            WORD * arg2 )
```

Definition at line 3184 of file tools.c.

4.118.3.82 CompArg()

```
int CompArg (
            WORD * s1,
            WORD * s2 )
```

Definition at line 3215 of file tools.c.

4.118.3.83 TimeWallClock()

```
LONG TimeWallClock (
            WORD par )
```

Returns the wall-clock time.

Parameters

par	If zero, the wall-clock time will be reset to 0.

Returns

The wall-clock time in centiseconds.

Definition at line 3377 of file tools.c.

Referenced by DoCheckpoint(), DoRecovery(), and WriteStats().

4.118.3.84 TimeChildren()

```
LONG TimeChildren (
            WORD par )
```

Definition at line 3400 of file tools.c.

4.118.3.85 TimeCPU()

```
LONG TimeCPU (
            WORD par )
```

Returns the CPU time.

Parameters

par	If zero, the CPU time will be reset to 0.

Returns

The CPU time in milliseconds.

Definition at line 3418 of file tools.c.

Referenced by PF_GetSlaveTimes(), PF_Processor(), and WriteStats().

4.118.3.86 Crash()

```
int Crash ( )
```

Definition at line 3701 of file tools.c.

4.118.3.87 TestTerm()

```
int TestTerm (
            WORD * term )
```

Tests the consistency of the term. Returns 0 when the term is OK. Any nonzero value is trouble. In the current version the testing isn't 100% complete. For instance, we don't check the validity of the symbols nor do we check the range of their powers. Etc. This should be extended when the need is there.

Parameters

term	the term to be tested

Definition at line 3729 of file tools.c.

References TestTerm().

Referenced by TestTerm().

        #] ReadFile :
        #[ ReadPosFile :

        Gets words from a file(handle).
        First tries to get the information from the buffers.
        Reads a file at a position. Updates the position.
```

```
        Places a lock in the case of multithreading.
        Exists for multiple reading from the same file.
        size is the number of WORDs to read!!!!

        We may need some strategy in the caching. This routine is used from
        GetOneTerm only. The problem is when it reads brackets and the
        brackets are read backwards. This is very uneconomical because
        each time it may read a large buffer.
        On the other hand, reading piece by piece in GetOneTerm takes
        much overhead as well.
        Two strategies come to mind:
        1: keep things as they are but limit the size of the buffers.
        2: have the position of 'pos' at about 1/3 of the buffer.
           this is of course guess work.
        Currently we have implemented the first method by creating the
        setup parameter threadscratchsize with the default value 100K.
        In the test program much bigger values gave a slower program.

4.120.1 Detailed Description

Routines that deal with the transform statement and its varieties.

Definition in file transform.c.

4.120.2 Function Documentation

4.120.2.1 CoTransform()

```
int CoTransform (
            UBYTE * in )
```

Definition at line 87 of file transform.c.

4.120.2.2 RunTransform()

```
WORD RunTransform (
            PHEAD WORD * term,
            WORD * params )
```

Definition at line 689 of file transform.c.

4.120.2.3 RunEncode()

```
WORD RunEncode (
            PHEAD WORD * fun,
            WORD * args,
            WORD * info )
```

Definition at line 922 of file transform.c.

4.120.2.4 RunDecode()

```
WORD RunDecode (
            PHEAD WORD * fun,
            WORD * args,
            WORD * info )
```

Definition at line 1109 of file transform.c.

4.120.2.5 RunReplace()

```
WORD RunReplace (
            PHEAD WORD * fun,
            WORD * args,
            WORD * info )
```

Definition at line 1279 of file transform.c.

4.120.2.6 RunImplode()

```
WORD RunImplode (
            WORD * fun,
            WORD * args )
```

Definition at line 1757 of file transform.c.

4.120.2.7 RunExplode()

```
WORD RunExplode (
            PHEAD WORD * fun,
            WORD * args )
```

Definition at line 1958 of file transform.c.

4.120.2.8 RunPermute()

```
WORD RunPermute (
            PHEAD WORD * fun,
            WORD * args,
            WORD * info )
```

Definition at line 2072 of file transform.c.

4.120.2.9 RunReverse()

```
WORD RunReverse (
            PHEAD WORD * fun,
            WORD * args )
```

Definition at line 2299 of file transform.c.

4.120.2.10 RunDedup()

```
WORD RunDedup (
            PHEAD WORD * fun,
            WORD * args )
```

Definition at line 2386 of file transform.c.

4.120.2.11 RunCycle()

```
WORD RunCycle (
            PHEAD WORD * fun,
            WORD * args,
            WORD * info )
```

Definition at line 2475 of file transform.c.

4.120.2.12 RunAddArg()

```
WORD RunAddArg (
            PHEAD WORD * fun,
            WORD * args )
```

Definition at line 2627 of file transform.c.

4.120.2.13 RunMulArg()

```
WORD RunMulArg (
            PHEAD WORD * fun,
            WORD * args )
```

Definition at line 2710 of file transform.c.

4.120.2.14 RunIsLyndon()

```
WORD RunIsLyndon (
            PHEAD WORD * fun,
            WORD * args,
            int par )
```

Definition at line 2849 of file transform.c.

4.120.2.15 RunToLyndon()

```
WORD RunToLyndon (
            PHEAD WORD * fun,
            WORD * args,
            int par )
```

Definition at line 2927 of file transform.c.

4.120.2.16 RunDropArg()

```
WORD RunDropArg (
            PHEAD WORD * fun,
            WORD * args )
```

Definition at line 3039 of file transform.c.

4.120.2.17 RunSelectArg()

```
WORD RunSelectArg (
            PHEAD WORD * fun,
            WORD * args )
```

Definition at line 3065 of file transform.c.

4.120.2.18 TestArgNum()

```
int TestArgNum (
            int n,
            int totarg,
            WORD * args )
```

Definition at line 3103 of file transform.c.

4.120.2.19 PutArgInScratch()

```
WORD PutArgInScratch (
            WORD * arg,
            UWORD * scrat )
```

Definition at line 3172 of file transform.c.

4.120.2.20 ReadRange()

```
UBYTE * ReadRange (
            UBYTE * s,
            WORD * out,
            int par )
```

Definition at line 3208 of file transform.c.

4.120.2.21 FindRange()

```
int FindRange (
            PHEAD WORD * args,
            WORD * arg1,
            WORD * arg2,
            WORD totarg )
```

Definition at line 3368 of file transform.c.

00036
00037 /*
00038     #] Includes :
00039     #[ Transform :
00040         #[ Intro :
00041
00042         Here are the routines for the transform statement. This is a
00043         group of transformations on function arguments or groups of
00044         function arguments. The purpose of this command is that it
00045         avoids repetitive pattern matching.
00046         Syntax:
00047             Transform,SetOfFunctions,OneOrMoreTransformations;
00048         Each transformation is given by
00049             Replace(argfirst,arglast)=(,,)
00050             Encode(argfirst,arglast):base=#
```

```
            Decode(argfirst,arglast):base=#
            Implode(argfirst,arglast)
            Explode(argfirst,arglast)
            Permute(cycle)(cycle)(cycle)...(cycle)
            Reverse(argfirst,arglast)
            Dedup(argfirst,arglast)
            Cycle(argfirst,arglast)=+/-num
            IsLyndon(argfirst,arglast)=(yes,no)
            ToLyndon(argfirst,arglast)=(yes,no)
        In replace the extra information is
            a replace_() without the name of the replace_ function.
            This can be as in (0,1,1,0) or (xarg_,1-xarg_) to indicate
            a symbolic argument or (x,y,y,x) to exchange x and y, etc.
        In Encode and Decode argfirst is the most significant 'word' and
        arglast is the least significant 'word'.
        Note that we need to introduce the generic symbolic arguments xarg_,
        parg_, iarg_ and farg_.
        Examples:
            Transform,{H,E}
                    ,Replace(1:'WEIGHT')=(0,1,1,0)
                    ,Encode(1:'WEIGHT')=base(2);
            Transform,{H,E}
                    ,Decode(1:'WEIGHT')=base(3)
                    ,Replace(1:'WEIGHT')=(2,-1,1,0,0,1);
        Others that can be added:
            symmetrize?

        6-may-2016: Changed MAXPOSITIVE2 into MAXPOSITIVE4. This makes room
                    for the use of dollar variables as arguments.

4.126.1 Detailed Description

Contains a number of defines to make the coding easier. Especially the defines for the use of the lists are very nice. And of course the AC for A.C and AT for either A.T of B->T are indispensible to keep FORM and TFORM in one set of sources.

Definition in file variable.h.

4.128.1 Detailed Description

An implementation of dynamic array.

Example:
```
size_t i;
Vector(int, vec);
VectorPushBack(vec, 1);
VectorPushBack(vec, 2);
VectorPushBack(vec, 3);
for ( i = 0; i < VectorSize(vec); i++ )
  printf("%d\n", VectorPtr(vec)[i]);
VectorFree(vec);
```

Definition in file vector.h.

4.128.2 Macro Definition Documentation

4.128.2.1 VectorStruct

```
#define VectorStruct(
                T )
```

Value:
```
    struct { \
        T *ptr; \
        size_t size; \
        size_t capacity; \
    }
```

A struct for vector objects.

Parameters

T	the type of elements.

Definition at line 65 of file vector.h.

4.128.2.2 Vector

```
#define Vector(
                T,
                X )  VectorStruct(T) X = { NULL, 0, 0 }
```

Defines and initialises a vector X of the type T. The user must call VectorFree(X) after the use of X.

Parameters

T	the type of elements.
X	the name of vector object

Definition at line 84 of file vector.h.

4.128.2.3 DeclareVector

```
#define DeclareVector(
            T,
            X )  VectorStruct(T) X
```

Declares a vector X of the type T. The user must call VectorInit(X) before the use of X.

Parameters

T	the type of elements.
X	the name of vector object

Definition at line 99 of file vector.h.

4.128.2.4 VectorInit

```
#define VectorInit(
            X )
```

Value:

```
do { \
    (X).ptr = NULL; \
    (X).size = 0; \
    (X).capacity = 0; \
} while (0)
```

Initialises a vector X of the type T. The user must call VectorFree(X) after the use of X.

Parameters

X	the vector object.

Definition at line 113 of file vector.h.

4.128.2.5 VectorFree

```
#define VectorFree(
            X )
```

Value:

```
do { \
    M_free((X).ptr, "VectorFree:" #X); \
    (X).ptr = NULL; \
    (X).size = 0; \
    (X).capacity = 0; \
} while (0)
```

Frees the buffer allocated by the vector X.

Parameters

X	the vector object.

Definition at line 130 of file vector.h.

4.128.2.6 VectorPtr

```
#define VectorPtr(
            X )  ((X).ptr)
```

Returns the pointer to the buffer for the vector X. NULL when VectorCapacity(X) == 0.

Parameters

X	the vector object.

Returns

the pointer to the allocated buffer for the vector.

Definition at line 150 of file vector.h.

4.128.2.7 VectorFront

```
#define VectorFront(
            X )  ((X).ptr[0])
```

Returns the first element of the vector X. Undefined when VectorSize(X) == 0.

Parameters

X	the vector object.

Returns

the first element of the vector.

Definition at line 165 of file vector.h.

4.128.2.8 VectorBack

```
#define VectorBack(
            X )  ((X).ptr[(X).size - 1])
```

Returns the last element of the vector X. Undefined when VectorSize(X) == 0.

Parameters

X	the vector object.

Returns

the last element of the vector.

Definition at line 180 of file vector.h.

4.128.2.9 VectorSize

```
#define VectorSize(
            X )  ((X).size)
```

Returns the size of the vector X.

Parameters

X	the vector object.

Returns

the size of the vetor.

Definition at line 194 of file vector.h.

4.128.2.10 VectorCapacity

```
#define VectorCapacity(
            X )  ((X).capacity)
```

Returns the capacity (the number of the already allocated elements) of the vector X.

Parameters

X	the vector object.

Returns

the capacity of the vetor.

Definition at line 208 of file vector.h.

4.128.2.11 VectorEmpty

```
#define VectorEmpty(
            X )  ((X).size == 0)
```

Returns true the size of the vector X is zero.

Parameters

X	the vector object.

Returns

true if the vector has no elements, false otherwise.

Definition at line 222 of file vector.h.

4.128.2.12 VectorClear

```
#define VectorClear(
            X )  do { (X).size = 0; } while (0)
```

Sets the size of the vector X to zero.

Parameters

X	the vector object.

Definition at line 235 of file vector.h.

4.128.2.13 VectorReserve

```
#define VectorReserve(
            X,
            newcapacity )
```

Value:

```
do { \
    size_t v_tmp_newcapacity_ = (newcapacity); \
    if ( (X).capacity < v_tmp_newcapacity_ ) { \
        void *v_tmp_newptr_; \
        v_tmp_newcapacity_ = (v_tmp_newcapacity_ * 3) / 2; \
        if ( v_tmp_newcapacity_ < 4 ) v_tmp_newcapacity_ = 4; \
        v_tmp_newptr_ = Malloc1(sizeof((X).ptr[0]) * v_tmp_newcapacity_, "VectorReserve:" #X); \
        if ( (X).ptr != NULL ) { \
            memcpy(v_tmp_newptr_, (X).ptr, (X).size * sizeof((X).ptr[0])); \
            M_free((X).ptr, "VectorReserve:" #X); \
        } \
        (X).ptr = v_tmp_newptr_; \
        (X).capacity = v_tmp_newcapacity_; \
    } \
} while (0)
```

Requires that the capacity of the vector X is equal to or lager than newcapacity.

Parameters

X	the vector object.
newcapacity	the capacity to be reserved.

Definition at line 249 of file vector.h.

4.128.2.14 VectorPushBack

```
#define VectorPushBack(
            X,
            x )
```

Value:

```
do { \
    VectorReserve((X), (X).size + 1); \
    (X).ptr[(X).size++] = (x); \
} while (0)
```

Adds an element x at the end of the vector X.

Parameters

X	the vector object.
x	the element to be added.

Definition at line 277 of file vector.h.

4.128.2.15 VectorPushBacks

```
#define VectorPushBacks(
            X,
            src,
            n )
```

Value:

```
do { \
    size_t v_tmp_n_ = (n); \
    VectorReserve((X), (X).size + v_tmp_n_); \
    memcpy((X).ptr + (X).size, (src), v_tmp_n_ * sizeof((X).ptr[0])); \
    (X).size += v_tmp_n_; \
} while (0)
```

Adds an n elements of src at the end of the vector X.

Parameters

X	the vector object.
src	the starting address of the buffer storing elements to be added.
n	the number of elements to be added.

Definition at line 295 of file vector.h.

4.128.2.16 VectorPopBack

```
#define VectorPopBack(
            X )  do { (X).size --; } while (0)
```

Removes the last element of the vector X. VectorSize(X) must be > 0.

Parameters

X	the vector object.

Definition at line 314 of file vector.h.

4.128.2.17 VectorInsert

```
#define VectorInsert(
            X,
            index,
            x )
```

Value:

```
do { \
    size_t v_tmp_index_ = (index); \
    VectorReserve((X), (X).size + 1); \
    memmove((X).ptr + v_tmp_index_ + 1, (X).ptr + v_tmp_index_, ((X).size - v_tmp_index_) *
  sizeof((X).ptr[0])); \
    (X).ptr[v_tmp_index_] = (x); \
    (X).size++; \
} while (0)
```

Inserts an element x at the specified index of the vector X. The index must be 0 <= index < VectorSize(X).

Parameters

X	the vector object.
index	the position at which the element will be inserted.
x	the element to be inserted.

Definition at line 330 of file vector.h.

4.128.2.18 VectorInserts

```
#define VectorInserts(
            X,
            index,
            src,
            n )
```

Value:

```
do { \
    size_t v_tmp_index_ = (index), v_tmp_n_ = (n); \
    VectorReserve((X), (X).size + v_tmp_n_); \
    memmove((X).ptr + v_tmp_index_ + v_tmp_n_, (X).ptr + v_tmp_index_, ((X).size - v_tmp_index_) *
  sizeof((X).ptr[0])); \
    memcpy((X).ptr + v_tmp_index_, (src), v_tmp_n_ * sizeof((X).ptr[0])); \
    (X).size += v_tmp_n_; \
} while (0)
```

Inserts an n elements of src at the specified index of the vector X. The index must be 0 <= index < VectorSize(X).

Parameters

X	the vector object.
index	the position at which the elements will be inserted.
src	the starting address of the buffer storing elements to be inserted.
n	the number of elements to be inserted.

Definition at line 353 of file vector.h.

4.128.2.19 VectorErase

```
#define VectorErase(
            X,
            index )
```

Value:

```
do { \
    size_t v_tmp_index_ = (index); \
    memmove((X).ptr + v_tmp_index_, (X).ptr + v_tmp_index_ + 1, ((X).size - v_tmp_index_ - 1) *
  sizeof((X).ptr[0])); \
    (X).size--; \
} while (0)
```

Removes an element at the specified index of the vector X. The index must be 0 <= index < VectorSize(X).

Parameters

X	the vector object.
index	the position of the element to be removed.

Definition at line 374 of file vector.h.

4.128.2.20 VectorErases

```
#define VectorErases(
            X,
            index,
            n )
```

Value:

```
do { \
    size_t v_tmp_index_ = (index), v_tmp_n_ = (n); \
    memmove((X).ptr + v_tmp_index_, (X).ptr + v_tmp_index_ + v_tmp_n_, ((X).size - v_tmp_index_ - 1) *
  sizeof((X).ptr[0])); \
    (X).size -= v_tmp_n_; \
} while (0)
```

Removes an n elements at the specified index of the vector X. The index must be 0 <= index < VectorSize(X) - n + 1.

Parameters

X	the vector object.
index	the starting position of the elements to be removed.
n	the number of elements to be removed.

Definition at line 394 of file vector.h.

4.130.1 Detailed Description

Contains the functions that deal with the wildcards. During the pattern matching there are two steps: 1: check that a wildcard substitution is correct (if there was already an assignment for this variable, it is the same; it is part of the proper set; it is the proper type of variables, etc.) 2: make the assignment In addition we have to be able to clear assignments. During execution we have to make the actual replacements (WildFill)

4.130.2.1 DEBUG

```
#define DEBUG(
              x )
```

Definition at line 44 of file wildcard.c.

4.130.3 Function Documentation

4.130.3.1 WildFill()

```
WORD WildFill (
            PHEAD WORD * to,
            WORD * from,
            WORD * sub )
```

Definition at line 65 of file wildcard.c.

4.130.3.2 ResolveSet()

```
WORD ResolveSet (
            PHEAD WORD * from,
            WORD * to,
            WORD * subs )
```

Definition at line 1333 of file wildcard.c.

4.130.3.3 ClearWild()

```
VOID ClearWild (
            PHEAD0  )
```

Definition at line 1490 of file wildcard.c.

4.130.3.4 AddWild()

```
WORD AddWild (
            PHEAD WORD oldnumber,
            WORD type,
            WORD newnumber )
```

Definition at line 1516 of file wildcard.c.

4.130.3.5 CheckWild()

```
WORD CheckWild (
            PHEAD WORD oldnumber,
            WORD type,
            WORD newnumber,
            WORD * newval )
```

Definition at line 1761 of file wildcard.c.

4.130.3.6 DenToFunction()

```
int DenToFunction (
            WORD * term,
            WORD numfun )
```

Definition at line 2472 of file wildcard.c.

/*
        #] WildFill :
        #[ ResolveSet :         WORD ResolveSet(from,to,subs)

        The set syntax is:
        SET,length,subterm,where,whichmember[,where,whichmember]

        setlength is 2*n+1 with n the number of set substitutions.
        length = setlength + subtermlength + 2

        At `where' is the number of the set and `whichmember' is the
        number of the element. This is still a symbol/dollar and we
        have to find the substitution in the wildcards.
        The output is the subterm in which the setelements have been
        substituted. This is ready for further wildcard substitutions.

/*
        #] AddWild :
        #[ CheckWild :          WORD CheckWild(oldnumber,type,newnumber,newval)

        Tests whether a wildcard assignment is allowed.
        A return value of zero means that it is allowed (nihil obstat).
        If the variable has been assigned already its existing
        assignment is returned in AN.oldvalue and AN.oldtype, which are
        global variables.

        Note the special problem with name?set[i]. Here we have to pass
        an extra assignment. This cannot be done via globals as we
        call CheckWild sometimes twice before calling AddWild.
        Trick: Check the assignment of the number and if OK put it
        in place, but don't alter the used flag (if needed).
        Then AddWild can alter the used flag but the value is there.
        As long as this trick is `hanging' we turn on the flag:
        `AN.WildReserve' which is either turned off by AddWild or by
        a failing call to CheckWild.

        With ARGTOARG the tensors give the number of arguments
        or-ed with EATTENSOR which is at least 8192.
