Definition at line 2621 of file [structs.h](#).

#### 3.2.2.3 S

```
struct S\_const AllGlobals::S
```

Definition at line 2622 of file [structs.h](#).

#### 3.2.2.4 R

```
struct R\_const AllGlobals::R
```

Definition at line 2623 of file [structs.h](#).

### 3.2.2.5 N

```
struct N_const AllGlobals::N
```

Definition at line 2624 of file [structs.h](#).

### 3.2.2.6 O

```
struct O_const AllGlobals::O
```

Definition at line 2625 of file [structs.h](#).

### 3.2.2.7 P

```
struct P_const AllGlobals::P
```

Definition at line 2626 of file [structs.h](#).

### 3.2.2.8 T

```
struct T_const AllGlobals::T
```

Definition at line 2627 of file [structs.h](#).

### 3.2.2.9 X

```
struct X_const AllGlobals::X
```

Definition at line 2628 of file [structs.h](#).

The documentation for this struct was generated from the following file:

- [structs.h](#)

## 3.3 ANode Class Reference

### 3.7.1 Detailed Description

The struct [bit\\_field](#) is used by [set\\_in](#), [set\\_set](#), [set\\_del](#) and [set\\_sub](#). They in turn are used in [pre.c](#) to toggle bits that indicate whether a character can be used as a separator of function arguments. This facility is used in the communication with external channels.

### 3.12.1 Detailed Description

The [C\\_const](#) struct is part of the global data and resides in the [ALLGLOBALS](#) struct A under the name #C. We see it used with the macro AC as in AC.exprnames. It contains variables that involve the compiler and objects set during compilation.

Definition at line 1697 of file [structs.h](#).

### 3.12.2 Field Documentation

#### 3.12.2.1 separators

`set_of_char C_const::separators`

Separators in #call and #do

Definition at line 1698 of file [structs.h](#).

#### 3.12.2.2 StoreFileSize

`POSITION C_const::StoreFileSize`

Definition at line 1699 of file [structs.h](#).

#### 3.12.2.3 dollarnames

`NAMETREE* C_const::dollarnames`

[D] Names of dollar variables

Definition at line 1700 of file [structs.h](#).

### 3.38.1 Detailed Description

The type FILEHANDLE is the struct that controls all relevant information of a file, whether it is open or not. The file may even not yet exist. There is a system of caches (PObuffer) and as long as the information to be written still fits inside the cache the file may never be created. There are variables that can store information about different types of files, like scratch files or sort files. Depending on what is available in the system we may also have information about gzip compression (currently sort file only) or locks (TFORM).

- [INDEXENTRY](#) expression [[INFILEINDEX](#)]
- [SBYTE](#) empty [[EMPTYININDEX](#)]

### 3.40.1 Detailed Description

Defines the structure of a file index in store-files and save-files.

It contains several entries (see struct [InDeXeNtRy](#)) up to a maximum of [INFILEINDEX](#).

The variable number has been made of type [POSITION](#) to avoid padding problems with some types of computers/↔ OS and keep system independence of the .sav files.

This struct is always 512 bytes long.

### 3.41.1 Detailed Description

The FIXEDGLOBALS struct is an anachronism. It started as the struct with global variables that needed initialization. It contains the elements `Operation` and `OperaFind` which define a very early way of automatically jumping to the proper operation. We find the results of it in parts of the file [opera.c](#). Later operations were treated differently in a more transparent way. We never changed the existing code. The most important part is currently the `cTable` which is used intensively in the compiler.

### 3.60.1 Detailed Description

The [M\\_const](#) struct is part of the global data and resides in the [ALLGLOBALS](#) struct A under the name #M. We see it used with the macro AM as in AM.S0. It contains global settings at startup or .clear.

### 3.79.1 Detailed Description

The [N\\_const](#) struct is part of the global data and resides either in the ALLGLOBALS struct A, or the ALLPRIVATEs struct B (TFORM) under the name N We see it used with the macro AN as in AN.RepFunNum It has variables that are private to each thread and are used as temporary storage during the expansion of the terms tree.

### Data Fields

- LONG [name](#)
- WORD [parent](#)
- WORD [left](#)
- WORD [right](#)
- WORD [balance](#)
- WORD [type](#)
- WORD [number](#)

### 3.81.1 Detailed Description

The names of variables are kept in an array. Elements of type [NAMENODE](#) define a tree (that is kept balanced) that make it easy and fast to look for variables. See also [NAMETREE](#).

Definition at line 247 of file [structs.h](#).

### 3.81.2 Field Documentation

- `WORD headnode`

### 3.83.1 Detailed Description

A struct of type [NAMETREE](#) controls a complete (balanced) tree of names for the compiler. The compiler maintains several of such trees and the system has been set up in such a way that one could define more of them if we ever want to work with local name spaces.

Definition at line 265 of file [structs.h](#).

### 3.83.2 Field Documentation

#### 3.83.2.1 namenode

```
NAMENODE* NaMeTree::namenode
```

[D] Vector of [NAMENODE](#)'s. Number of elements is [nodesize](#). =0 if no memory has been allocated.

Definition at line 266 of file [structs.h](#).

#### 3.83.2.2 namebuffer

```
UBYTE* NaMeTree::namebuffer
```

[D] Buffer that holds all the name strings referred to by the [NAMENODE](#)'s. Allocation size is [namesize](#). =0 if no memory has been allocated.

Definition at line 268 of file [structs.h](#).

#### 3.83.2.3 nodesize

```
LONG NaMeTree::nodesize
```

Maximum number of elements in [namenode](#).

Definition at line 271 of file [structs.h](#).

#### 3.83.2.4 nodefill

```
LONG NaMeTree::nodefill
```

Number of currently used nodes in [namenode](#).

Definition at line 272 of file [structs.h](#).

#### 3.83.2.5 namesize

```
LONG NaMeTree::namesize
```

Allocation size of [namebuffer](#) in bytes.

Definition at line 273 of file [structs.h](#).

### 3.83.2.6 namefill

```
LONG NaMeTree::namefill

Definition at line 276 of file [structs.h](#).

### 3.83.2.9 globalnamefill

```
LONG NaMeTree::globalnamefill
```

Set by .global statement to the value of [namefill](#). When a .store command is processed, this value will be used to reset namefill.

Definition at line 277 of file [structs.h](#).

### 3.83.2.10 globalnodefill

```
LONG NaMeTree::globalnodefill
```

Same usage as [globalnamefill](#), but for nodefill.

Definition at line 279 of file [structs.h](#).

### 3.83.2.11 clearnamefill

```
LONG NaMeTree::clearnamefill
```

Marks the reset point used by the .clear statement.

Definition at line 280 of file [structs.h](#).

### 3.83.2.12 clearnodefill

```
LONG NaMeTree::clearnodefill
```

Marks the reset point used by the .clear statement.

Definition at line 281 of file [structs.h](#).

### 3.83.2.13 headnode

```
WORD NaMeTree::headnode
```

Offset in [namenode](#) of head node. ==-1 if tree is empty.

Definition at line 282 of file [structs.h](#).

### 3.92.1 Detailed Description

The [O\\_const](#) struct is part of the global data and resides in the ALLGLOBALS struct A under the name O We see it used with the macro AO as in AO.OutputLine It contains variables that involve the writing of text output and save/store files.

## Data Fields

- int `type`

- int `improve`
- vector< WORD > `coeff`
- vector< int > `eqnidxs`

### 3.95.1 Detailed Description

class Optimization

### 3.95.2 Description

This object represents an optimization. Its type is a number in the range 0 to 5. Depending on this type, the variables `arg1`, `arg2` and `coeff` indicate:

type==0 : optimization of the form  $x[\text{arg1}] \wedge \text{arg2}$  (coeff=empty) type==1 : optimization of the form  $x[\text{arg1}] * x[\text{arg2}]$  (coeff=empty) type==2 : optimization of the form  $x[\text{arg1}] * \text{coeff}$  (arg2=0) type==3 : optimization of the form  $x[\text{arg1}] + \text{coeff}$  (arg2=0) type==4 : optimization of the form  $x[\text{arg1}] + x[\text{arg2}]$  (coeff=empty) type==5 : optimization of the form  $x[\text{arg1}] - x[\text{arg2}]$  (coeff=empty)

Here, "`x[arg]`" represents a symbol (if positive) or an extrasymbol (if negative). The represented symbol's id is  $\text{ABS}(x[\text{arg}]) - 1$ .

"eqns" is a list of equation, where this optimization can be performed.

"improve" is the total improvement of this optimization.

## 3.112.6 Description

This routine determines which multiplication routine to use for multiplying two polynomials. The logic is as follows:

- If a or b consists of only one term, call `mul_one_term`;
- Otherwise, if both are univariate and dense, call `mul_univar`;
- Otherwise, call `mul_heap`.

Multiplication of polynomials with a heap

## 3.112.8 Description

Multiplies two multivariate polynomials. The next element of the product is efficiently determined by using a heap. If the product of the maximum power in all variables is small, a hash table is used to add equal terms for extra speed.

A heap element h is formatted as follows:

- h[0] = index in a
- h[1] = index in b
- h[2] = hash code (-1 if no hash is used)
- h[3] = length of coefficient with sign
- h[4...4+AN.poly\_num\_vars-1] = powers

- $h[4+AN.poly\_num\_vars...4+h[3]-1]$  = coefficient

Division of dense univariate polynomials.

### 3.112.9 Description

Divides two dense univariate polynomials. For each power, the method collects all terms that result in that power.

Relevant formula  $[Q=A/B, P=\text{SUM}(p_i \cdot x^i), n=\text{deg}(A), m=\text{deg}(B)]: q_k = [a_{m+k} - \text{SUM}(i=k+1 \dots n-m, b_{m+k-i} \cdot q_i)] / b_m$

```

Division of polynomials with a heap

### 3.112.10 Description

Divides two multivariate polynomials. The next element of the quotient/remainder is efficiently determined by using a heap. If the product of the maximum power in all variables is small, a hash table is used to add equal terms for extra speed.

If the input flag `check_div` is set then if the result of any coefficient division results in a non-zero remainder (indicating that division has failed over the integers) the output flag `div_fail` will be set and the division will be terminated early (`q`, `r` will be incorrect). If `check_div` is not set then non-zero remainders from coefficient division will be written into `r`.

A heap element `h` is formatted as follows:

- $h[0]$  = index in  $a$
- $h[1]$  = index in  $b$
- $h[2] = -1$  (no hash is used)
- $h[3]$  = length of coefficient with sign
- $h[4 \dots 4 + \text{AN.poly\_num\_vars} - 1]$  = powers
- $h[4 + \text{AN.poly\_num\_vars} \dots 4 + h[3] - 1]$  = coefficient

Note: the hashing trick as in multiplication cannot be used easily, since there is no tight upperbound on the exponents in the answer.

### 3.124.1 Detailed Description

Each setup parameter has one element of the struct [SETUPPARAMETERS](#) assigned to it. By binary search in the array of them we can then locate the proper element by name. We have to assume that two ints make a long and either one or two longs make a pointer. The long before the ints and padding gives a problem in the initialization.

### 3.127.1 Detailed Description

The struct SORTING is used to control a sort operation. It includes a small and a large buffer and arrays for keeping track of various stages of the (merge) sorts. Each sort level has its own struct and different levels can have different sizes for its arrays. Also different threads have their own set of SORTING structs.

### 3.131.1 Detailed Description

Defines the structure of the file header for store-files and save-files.

The first 8 bytes serve as a unique mark to identity save-files that contain such a header. Older versions of FORM don't have this header and will write the POSITION of the next file index (struct [FiLeInDeX](#)) here, which is always different from this pattern.

It is always 512 bytes long.

### 3.132.1 Detailed Description

Input is read from 'streams' which are represented by objects of type STREAM. A stream can be a file, a do-loop, a procedure, the string value of a preprocessor variable ..... When a new stream is opened we have to keep information about where to fall back in the parent stream to allow this to happen even in the middle of reading names etc as would be the case with a`i`b

### 3.150.1 Detailed Description

The struct TRACES keeps track of the progress during the expansion of a 4-dimensional trace. Each time a term gets generated the expansion tree continues in the next statement. When it returns it has to know where to continue. The 4-dimensional traces are more complicated than the n-dimensional traces (see TRACEN) because of the extra tricks that can be used. They are responsible for the shorter final expressions.

### 3.151.1 Detailed Description

The subexpressions in the compiler are kept track of in a (balanced) tree to reduce the need for subexpressions and hence save much space in large rhs expressions (like when we have xxxxxx occurrences of objects like  $f(x+1, x+1)$  in which each  $x+1$  becomes a subexpression. The struct that controls this tree is COMPTREE.

Definition in file [argument.c](#).

### 4.1.2 Macro Definition Documentation

#### 4.1.2.1 NEWORDER

```
#define NEWORDER
```

Factorizes an argument in general notation (meaning that the first word of the argument is a positive size indicator)  
Input (argin): pointer to the complete argument [Output](#) (argout): Pointer to where the output should be written. This is in the WorkSpace Return value should be negative if anything goes wrong.

The notation of the output should be a string of arguments terminated by the number zero.

Originally we sorted in a way that the constants came last. This gave conflicts with the dollar and expression factorizations (in the expressions we wanted the zero first and then followed by the constants).

#### 4.1.3.5 ArgFactorize()

```
int ArgFactorize (
    PHEAD WORD * argin,
    WORD * argout )
```

Definition at line 2060 of file [argument.c](#).

#### 4.1.3.6 FindArg()

```
WORD FindArg (
    PHEAD WORD * a )
```

Looks the argument up in the (workers) table. If it is found the number in the table is returned (plus one to make it positive). If it is not found we look in the compiler provided table. If it is found - the number in the table is returned (minus one to make it negative). If in neither table we return zero.

Definition at line 2513 of file [argument.c](#).

#### 4.1.3.7 InsertArg()

```
WORD InsertArg (
    PHEAD WORD * argin,
    WORD * argout,
    int par )
```

Inserts the argument into the (workers) table. If the table is too full we eliminate half of it. The eliminated elements are the ones that have not been used most recently, weighted by their total use and age(?). If par == 0 it inserts in the regular factorization cache If par == 1 it inserts in the cache defined with the FactorCache statement

Definition at line 2537 of file [argument.c](#).

Here is the call graph for this function:

#### 4.1.3.8 CleanupArgCache()

```
int CleanupArgCache (
    PHEAD WORD bufnum )
```

Cleans up the argument factorization cache. We throw half the elements. For a weight of what we want to keep we use the product of usage and the number in the buffer.

Definition at line 2572 of file [argument.c](#).

int ArgSymbolMerge (
    WORD * t1,
    WORD * t2 )
```

Definition at line 2643 of file [argument.c](#).

#### 4.1.3.10 ArgDotproductMerge()

```
int ArgDotproductMerge (
    WORD * t1,
    WORD * t2 )
```

Definition at line 2698 of file [argument.c](#).

#### 4.1.3.11 TakeArgContent()

```
WORD * TakeArgContent (
    PHEAD WORD * argin,
    WORD * argout )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. The common pieces are put in argout as a sequence of arguments. The part with the multiple terms that are now relative prime is put in argfree which is allocated via TermMalloc and is given as the return value. The difference with the old code is that negative powers are always removed. Hence it is as in MakeInteger in which only numerators will be left: now only zero or positive powers will be remaining.

Definition at line 2766 of file [argument.c](#).

References [EndSort\(\)](#), [MakeInteger\(\)](#), [MakeMod\(\)](#), [NewSort\(\)](#), and [StoreTerm\(\)](#).

Here is the call graph for this function:

#### 4.1.3.12 MakeInteger()

```
WORD * MakeInteger (
    PHEAD WORD * argin,
    WORD * argout,
    WORD * argfree )
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in argin. The number that comes out should go to argout. The new pointer in the argout buffer is the return value. The normalized argument is in argfree.

Definition at line 3312 of file [argument.c](#).

Referenced by [TakeArgContent\(\)](#).

#### 4.1.3.13 MakeMod()

```
WORD * MakeMod (
    PHEAD WORD * argin,
    WORD * argout,
    WORD * argfree )
```

Similar to MakeInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

#### 4.1.3.14 SortWeights()

```
void SortWeights (
    LONG * weights,
    LONG * extraspace,
    WORD number )
```

Sorts an array of LONGS in the same way SplitMerge (in [sort.c](#)) works We use gradual division in two.

### 4.5.1 Detailed Description

Contains all functions that deal with the recovery mechanism controlled and activated by the On Checkpoint switch.

The main function are DoCheckpoint, DoRecovery, and DoSnapshot. If the checkpoints are activated DoCheckpoint is called every time a module is finished executing. If the conditions for the creation of a recovery snapshot are met DoCheckpoint calls DoSnapshot. DoRecovery is called once when FORM starts up with the command line argument -R. Most of the other code contains debugging facilities that are only compiled if the macro PRINTDEBUG is defined.

The recovery mechanism is atomic, i.e. only if everything went well, the final recovery file is created (and the older one overwritten) in a single step (copying). If some errors occur, a warning is issued and the program continues without having created a new recovery file. The only situation in which the creation of the recovery data leads to a termination of the running program is if not enough disk or memory space is left.

For ParFORM each slave creates its own recovery file, sends it to the master and then it deletes the recovery file. The master stores all the recovery files and on recovery it feeds these files to the slaves. It is nearly impossible to recover after some MPI fault so ParFORM terminates on any recovery failure.

DoRecovery and DoSnapshot do the loading and saving of the recovery data, respectively. Every change in one functions needs to be accompanied by the appropriate change in the other function. The structure of both functions is quite similar. They handle the relevant global structs one after the other and then care about the copying of the hide and scratch files.

The names of the recovery, scratch and hide files are hard-coded in the variables in fold "filenames and system commands".

If the global structs AM,AP,AC,AR are changed, DoRecovery and DoSnapshot usually also have to be changed. Some structs are read/written as a whole (AP,AC), some are read/written only partly as a selection of their individual elements (AM,AR). If AM or AR have been changed by adding or removing an element that is important for the runtime status, then the reading/writing statements have to be added to or removed from DoRecovery and DoSnapshot. If AP or AC are changed, then for non-pointer variables (in the case of a struct it also means that none of its elements is a pointer) nothing has to be changed in the functions here. If pointers are involved, extra code has to be added (or removed). See the comments of DoRecovery and DoSnapshot.

### 4.5.3 Function Documentation

#### 4.5.3.1 CheckRecoveryFile()

```
int CheckRecoveryFile (  
    void )
```

Checks whether a snapshot/recovery file exists. Returns 1 if it exists, 0 otherwise.

Definition at line 278 of file [checkpoint.c](#).

References [RecoveryFilename\(\)](#).

Here is the call graph for this function:

#### 4.5.3.2 DeleteRecoveryFile()

```
void DeleteRecoveryFile (  
    void )
```

Deletes the recovery files. It is called by `CleanUp()` in the case of a successful completion.

Definition at line 333 of file [checkpoint.c](#).

#### 4.5.3.3 RecoveryFilename()

```
char * RecoveryFilename (  
    void )
```

Returns pointer to recovery filename.

Definition at line 364 of file [checkpoint.c](#).

Referenced by [CheckRecoveryFile\(\)](#), and [DoRecovery\(\)](#).

#### 4.5.3.4 InitRecovery()

```
void InitRecovery (
    void )
```

Sets up the strings for the filenames of the recovery files. This functions should only be called once to avoid memory leaks and after AM.TempDir has been initialized.

Definition at line 399 of file [checkpoint.c](#).

#### 4.5.3.5 fwrite\_cached()

```
size_t fwrite_cached (
    const void * ptr,
    size_t size,
    size_t nmemb,
    FILE * fd )
```

Definition at line 1222 of file [checkpoint.c](#).

#### 4.5.3.6 flush\_cache()

```
size_t flush_cache (
    FILE * fd )
```

Definition at line 1247 of file [checkpoint.c](#).

#### 4.5.3.7 DoRecovery()

```
int DoRecovery (
    int * moduletype )
```

Reads from the recovery file and restores all necessary variables and states in FORM, so that the execution can recommence in preprocessor() as if no restart of FORM had occurred.

The recovery file is read into memory as a whole. The pointer p then points into this memory at the next non-processed data. The macros by which variables are restored, like R\_SET, automatically increase p appropriately.

If something goes wrong, the function returns with a non-zero value.

Allocated memory that would be lost when overwriting the global structs with data from the file is freed first. A major part of the code deals with the restoration of pointers. The idiom we use is to memorize the original pointer value (org), allocate new memory and copy the data from the file into this memory, calculate the offset between the old pointer value and the new allocated memory position (ofs), and then correct all affected pointers (+=ofs).

We rely on the fact that several variables (especially in AM) are already assigned the correct values by the startup functions. That means, in principle, that a change in the setup files between snapshot creation and recovery will be noticed.

### 4.9.1 Detailed Description

Compiler routines for most statements that don't involve algebraic expressions. Exceptions: all routines involving declarations are in the file [names.c](#) When making new statements one can add the compiler routines here and have a look whether there is already a routine that is similar. In that case one can make a copy and modify it.

## 4.9.2 Function Documentation

### 4.9.2.1 CoFormat()

```
int CoFormat (
    UBYTE * s )
```

Definition at line [151](#) of file [compcomm.c](#).

### 4.9.2.2 CoCollect()

```
int CoCollect (
    UBYTE * s )
```

Definition at line [426](#) of file [compcomm.c](#).

### 4.9.2.3 setonoff()

```
int setonoff (
    UBYTE * s,
    int * flag,
    int onvalue,
    int offvalue )
```

Definition at line [488](#) of file [compcomm.c](#).

#### 4.9.2.4 CoCompress()

```
int CoCompress (
    UBYTE * s )
```

Definition at line 504 of file [compcomm.c](#).

#### 4.9.2.5 CoFlags()

```
int CoFlags (
    UBYTE * s,
    int value )
```

Definition at line 553 of file [compcomm.c](#).

#### 4.9.2.6 CoOff()

```
int CoOff (
    UBYTE * s )
```

Definition at line 588 of file [compcomm.c](#).

#### 4.9.2.7 CoOn()

```
int CoOn (
    UBYTE * s )
```

Definition at line 654 of file [compcomm.c](#).

#### 4.9.2.8 CoInsideFirst()

```
int CoInsideFirst (
    UBYTE * s )
```

Definition at line 926 of file [compcomm.c](#).

#### 4.9.2.9 CoProperCount()

```
int CoProperCount (
    UBYTE * s )
```

Definition at line 933 of file [compcomm.c](#).

#### 4.9.2.10 CoDelete()

```
int CoDelete (
    UBYTE * s )
```

Definition at line 940 of file [compcomm.c](#).

#### 4.9.2.11 CoKeep()

```
int CoKeep (
    UBYTE * s )
```

Definition at line 985 of file [compcomm.c](#).

#### 4.9.2.12 CoFixIndex()

```
int CoFixIndex (
    UBYTE * s )
```

Definition at line 997 of file [compcomm.c](#).

#### 4.9.2.13 CoMetric()

```
int CoMetric (
    UBYTE * s )
```

Definition at line 1031 of file [compcomm.c](#).

#### 4.9.2.14 DoPrint()

```
int DoPrint (
    UBYTE * s,
    int par )
```

Definition at line 1039 of file [compcomm.c](#).

#### 4.9.2.15 CoPrint()

```
int CoPrint (
    UBYTE * s )
```

Definition at line 1255 of file [compcomm.c](#).

#### 4.9.2.16 CoPrintB()

```
int CoPrintB (
    UBYTE * s )
```

Definition at line 1262 of file [compcomm.c](#).

#### 4.9.2.17 CoNPrint()

```
int CoNPrint (
    UBYTE * s )
```

Definition at line 1269 of file [compcomm.c](#).

#### 4.9.2.18 CoPushHide()

```
int CoPushHide (
    UBYTE * s )
```

Definition at line 1276 of file [compcomm.c](#).

#### 4.9.2.19 CoPopHide()

```
int CoPopHide (
    UBYTE * s )
```

Definition at line 1320 of file [compcomm.c](#).

#### 4.9.2.20 SetExprCases()

```
int SetExprCases (
    int par,
    int setunset,
    int val )
```

Definition at line 1355 of file [compcomm.c](#).

#### 4.9.2.21 SetExpr()

```
int SetExpr (
    UBYTE * s,
    int setunset,
    int par )
```

Definition at line 1501 of file [compcomm.c](#).

#### 4.9.2.22 CoDrop()

```
int CoDrop (
    UBYTE * s )
```

Definition at line 1546 of file [compcomm.c](#).

#### 4.9.2.23 CoNoDrop()

```
int CoNoDrop (
    UBYTE * s )
```

Definition at line 1553 of file [compcomm.c](#).

#### 4.9.2.24 CoSkip()

```
int CoSkip (
    UBYTE * s )
```

Definition at line 1560 of file [compcomm.c](#).

#### 4.9.2.25 CoNoSkip()

```
int CoNoSkip (
    UBYTE * s )
```

Definition at line 1567 of file [compcomm.c](#).

#### 4.9.2.26 CoHide()

```
int CoHide (
    UBYTE * inp )
```

Definition at line 1574 of file [compcomm.c](#).

#### 4.9.2.27 CoIntoHide()

```
int CoIntoHide (
    UBYTE * inp )
```

Definition at line 1592 of file [compcomm.c](#).

#### 4.9.2.28 CoNoHide()

```
int CoNoHide (
    UBYTE * inp )
```

Definition at line 1610 of file [compcomm.c](#).

#### 4.9.2.29 CoUnHide()

```
int CoUnHide (
    UBYTE * inp )
```

Definition at line 1617 of file [compcomm.c](#).

#### 4.9.2.30 CoNoUnHide()

```
int CoNoUnHide (
    UBYTE * inp )
```

Definition at line 1624 of file [compcomm.c](#).

#### 4.9.2.31 AddToCom()

```
void AddToCom (
    int n,
    WORD * array )
```

Definition at line 1631 of file [compcomm.c](#).

#### 4.9.2.32 AddComString()

```
int AddComString (
    int n,
    WORD * array,
    UBYTE * thestring,
    int par )
```

Definition at line 1646 of file [compcomm.c](#).

#### 4.9.2.33 Add2ComStrings()

```
int Add2ComStrings (
    int n,
    WORD * array,
    UBYTE * string1,
    UBYTE * string2 )
```

Definition at line 1705 of file [compcomm.c](#).

#### 4.9.2.34 CoDiscard()

```
int CoDiscard (
    UBYTE * s )
```

Definition at line 1746 of file [compcomm.c](#).

#### 4.9.2.35 CoContract()

```
int CoContract (
    UBYTE * s )
```

Definition at line 1769 of file [compcomm.c](#).

#### 4.9.2.36 CoGoTo()

```
int CoGoTo (
    UBYTE * inp )
```

Definition at line 1798 of file [compcomm.c](#).

#### 4.9.2.37 CoLabel()

```
int CoLabel (
    UBYTE * inp )
```

Definition at line 1817 of file [compcomm.c](#).

#### 4.9.2.38 DoArgument()

```
int DoArgument (
    UBYTE * s,
    int par )
```

Definition at line 1844 of file [compcomm.c](#).

#### 4.9.2.39 CoArgument()

```
int CoArgument (
    UBYTE * s )
```

Definition at line 2078 of file [compcomm.c](#).

#### 4.9.2.40 CoEndArgument()

```
int CoEndArgument (
    UBYTE * s )
```

Definition at line 2085 of file [compcomm.c](#).

#### 4.9.2.41 CoInside()

```
int CoInside (
    UBYTE * s )
```

Definition at line 2111 of file [compcomm.c](#).

#### 4.9.2.42 CoEndInside()

```
int CoEndInside (
    UBYTE * s )
```

Definition at line 2118 of file [compcomm.c](#).

#### 4.9.2.43 CoNormalize()

```
int CoNormalize (
    UBYTE * s )
```

Definition at line 2144 of file [compcomm.c](#).

#### 4.9.2.44 CoMakeInteger()

```
int CoMakeInteger (
    UBYTE * s )
```

Definition at line 2151 of file [compcomm.c](#).

#### 4.9.2.45 CoSplitArg()

```
int CoSplitArg (
    UBYTE * s )
```

Definition at line 2158 of file [compcomm.c](#).

#### 4.9.2.46 CoSplitFirstArg()

```
int CoSplitFirstArg (
    UBYTE * s )
```

Definition at line 2165 of file [compcomm.c](#).

#### 4.9.2.47 CoSplitLastArg()

```
int CoSplitLastArg (
    UBYTE * s )
```

Definition at line 2172 of file [compcomm.c](#).

#### 4.9.2.48 CoFactArg()

```
int CoFactArg (
    UBYTE * s )
```

Definition at line 2179 of file [compcomm.c](#).

#### 4.9.2.49 DoSymmetrize()

```
int DoSymmetrize (
    UBYTE * s,
    int par )
```

Definition at line 2199 of file [compcomm.c](#).

#### 4.9.2.50 CoSymmetrize()

```
int CoSymmetrize (
    UBYTE * s )
```

Definition at line 2319 of file [compcomm.c](#).

#### 4.9.2.51 CoAntiSymmetrize()

```
int CoAntiSymmetrize (  
    UBYTE * s )
```

Definition at line [2326](#) of file [compcomm.c](#).

#### 4.9.2.52 CoCycleSymmetrize()

```
int CoCycleSymmetrize (

### 4.11.1 Detailed Description

The heart of the compiler. It contains the tables of statements. It finds the statements in the tables and calls the proper routines. For algebraic expressions it runs the compilation by first calling the tokenizer, splitting things into subexpressions and generating the code. There is a system for recognizing already existing subexpressions. This economizes on the length of the output.

Note: the compiler of FORM doesn't attempt to normalize the input. Hence  $x+1$  and  $1+x$  are different objects during compilation. Similarly  $(a+b-b)$  will not be simplified to  $(a)$ .

00826 At this point we do not have to worry about subexpressions,
00827 sets, setelements, simple vs complicated function arguments
00828 simple vs complicated powers etc.
00829
00830 The variable 'first' indicates whether we are starting a new term
00831

00835 SETSET,size,subterm,relocation list
00836 in which the subterm should be ready to become a regular
00837 subterm in which the sets have been replaced by their element
00838 The relocation list consists of pairs of numbers:
00839 1: offset in the subterm, 2: the symbol n.
00840 Note that such a subterm can be a whole function with its arguments.
00841 We use the variable inset to indicate that we have something going.
00842 The relocation list is collected in the top of the Workspace.

00039
00040     Low level routines for dealing with zlib during sorting and handling
00041     the scratch files. Work started 5-sep-2005.
00042     The .sor file handling was more or less completed on 8-sep-2005
00043     The handling of the scratch files still needs some thinking.
00044     Complications are:
00045         gzip compression should be per expression, not per buffer.
00046         No gzip compression for expressions with a bracket index.
00047         Separate decompression buffers for expressions in the rhs.
00048         This last one will involve more buffer work and organization.
00049         Information about compression should be stored for each expr.
00050         (including what method/program was used)
00051     Note: Be careful with compression. By far the most compact method
00052     is the original problem....
00053
00054     #[ Variables :
00055
00056     The following variables are to contain the intermediate buffers
00057     for the inflation of the various patches in the sort file.
00058     There can be up to MaxFpatches (FilePatches in the setup) and hence
00059     we can have that many streams simultaneously. We set this up once
00060     and only when needed.

### 4.15.1 Detailed Description

Utility routines for the compiler.

Definition in file [comtool.c](#).

### 4.15.2 Function Documentation

#### 4.15.2.1 inicbufs()

```
int inicbufs (
    void )
```

Creates a new compiler buffer and returns its ID number.

##### Returns

The ID number for the new compiler buffer.

Definition at line 47 of file [comtool.c](#).

References [CbUf::boomlijst](#), [CbUf::Buffer](#), [CbUf::BufferSize](#), [CbUf::CanCommu](#), [CbUf::dimension](#), [CbUf::lhs](#), [CbUf::numdum](#), [CbUf::NumTerms](#), [CbUf::Pointer](#), [CbUf::rhs](#), and [CbUf::Top](#).

Referenced by [AddRHS\(\)](#), and [StartVariables\(\)](#).

#### 4.15.2.2 finishcbuf()

```
void finishcbuf (
    WORD num )
```

Frees a compiler buffer.

##### Parameters

|            |                                           |
|------------|-------------------------------------------|
| <i>num</i> | The ID number for the buffer to be freed. |
|------------|-------------------------------------------|

Definition at line 89 of file [comtool.c](#).

References [CbUf::boomlijst](#), [CbUf::Buffer](#), [CbUf::BufferSize](#), [CbUf::CanCommu](#), [CbUf::lhs](#), [CbUf::NumTerms](#), [CbUf::Pointer](#), [CbUf::rhs](#), and [CbUf::Top](#).

Referenced by [PF\\_BroadcastCBuf\(\)](#).

#### 4.15.2.3 clearcbuf()

```
void clearcbuf (
    WORD num )
```

Clears contents in a compiler buffer.

**Parameters**

|            |                                             |
|------------|---------------------------------------------|
| <i>num</i> | The ID number for the buffer to be cleared. |
|------------|---------------------------------------------|

Definition at line 116 of file [comtool.c](#).

References [CbUf::boomlijst](#), [CbUf::Buffer](#), [CbUf::Pointer](#), and [CbUf::rhs](#).

**4.15.2.4 DoubleCbuffer()**

```
WORD * DoubleCbuffer (
    int num,
    WORD * w,
    int par )
```

Doubles a compiler buffer.

**Parameters**

|            |                                                                                                                           |
|------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>num</i> | The ID number for the buffer to be doubled.                                                                               |
| <i>w</i>   | The pointer to the end (exclusive) of the current buffer. The contents in the range of [cbuf[num].Buffer,w) will be kept. |

Definition at line 143 of file [comtool.c](#).

References [CbUf::Buffer](#), [CbUf::BufferSize](#), [CbUf::lhs](#), [CbUf::Pointer](#), [CbUf::rhs](#), and [CbUf::Top](#).

Referenced by [AddNtoC\(\)](#), and [AddNtoL\(\)](#).

**4.15.2.5 AddLHS()**

```
WORD * AddLHS (
    int num )
```

Adds an LHS to a compiler buffer and returns the pointer to a buffer for the new LHS.

**Parameters**

|            |                                                  |
|------------|--------------------------------------------------|
| <i>num</i> | The ID number for the buffer to get another LHS. |
|------------|--------------------------------------------------|

Definition at line 188 of file [comtool.c](#).

References [CbUf::lhs](#), and [CbUf::Pointer](#).

Referenced by [AddNtoL\(\)](#).

**4.15.2.6 AddRHS()**

```
WORD * AddRHS (
    int num,
    int type )
```

Adds an RHS to a compiler buffer and returns the pointer to a buffer for the new RHS.

#### Parameters

|             |                                                   |
|-------------|---------------------------------------------------|
| <i>num</i>  | The ID number for the buffer to get another RHS.  |
| <i>type</i> | If 0, the subexpression tree will be reallocated. |

Definition at line 214 of file [comtool.c](#).

#### 4.15.2.7 AddNtoL()

```
int AddNtoL (
    int n,
    WORD * array )
```

Adds an LHS with the given data to the current compiler buffer.

#### Parameters

|              |                         |
|--------------|-------------------------|
| <i>n</i>     | The length of the data. |
| <i>array</i> | The data to be added.   |

#### Returns

0 if succeeds.

Definition at line 288 of file [comtool.c](#).

References [AddLHS\(\)](#), [DoubleCbuffer\(\)](#), [CbUf::Pointer](#), and [CbUf::Top](#).

#### 4.15.2.8 AddNtoC()

```

int AddNtoC (
    int bufnum,
    int n,
    WORD * array,
    int par )
  
```

Adds the given data to the last LHS/RHS in a compiler buffer.

##### Parameters

|               |                                                            |
|---------------|------------------------------------------------------------|
| <i>bufnum</i> | The ID number for the buffer where the data will be added. |
| <i>n</i>      | The length of the data.                                    |
| <i>array</i>  | The data to be added.                                      |

##### Returns

```

Definition at line 588 of file [comtool.c](#).

#### 4.15.2.13 IniFbuffer()

```
int IniFbuffer (
    WORD bufnum )
```

Initialize a factorization cache buffer. We set the size of the rhs and boomlijst buffers immediately to their final values.

00336      Routines for balanced tree searching and insertion.
00337      Compared to Knuth we have a parent link. This minimizes the
00338      number of compares. That is better for anything that is more
00339      complicated than just single numbers.
00340      There are no provisions for removing elements from the tree.
00341      The routines are:
00342      void RedoTree(size) Re-allocates the tree space. There will
00343                          be MaxTreeSize = size elements.
00344      void ClearTree()   Prunes the tree down to the root element.
00345      int InsTree(int,int) Searches for the requested element. If not found it
00346                          will allocate a new element, balance the tree if
00347                          necessary and return the called number.
00348                          If it was in the tree, it returns the tree 'value'.

### 4.19.1 Detailed Description

Contains macros and function declarations.

Definition in file [declare.h](#).

## 4.19.2 Macro Definition Documentation

### 4.19.2.1 MaX

```
#define MaX(  
    x,  
    y ) ((x) > (y) ? (x) : (y))
```

Definition at line 40 of file [declare.h](#).

### 4.19.2.2 MiN

```
#define MiN(  
    x,  
    y ) ((x) < (y) ? (x) : (y))
```

Definition at line 41 of file [declare.h](#).

### 4.19.2.3 ABS

```
#define ABS(  
    x ) ((x) < 0 ? -(x) : (x))
```

Definition at line 42 of file [declare.h](#).

### 4.19.2.4 SGN

```
#define SGN(  
    x ) ((x) > 0 ? 1 : (x) < 0 ? -1 : 0)
```

Definition at line 43 of file [declare.h](#).

### 4.19.2.5 REDLENG

```
#define REDLENG(  
    x ) (((x) < 0) ? ((x) + 1) : ((x) - 1)) / 2)
```

Definition at line 44 of file [declare.h](#).

### 4.19.2.6 INCLENG

```
#define INCLENG(  
    x ) (((x) < 0) ? ((x) * 2) - 1 : ((x) * 2) + 1)
```

Definition at line 45 of file [declare.h](#).

#### 4.19.2.7 GETCOEF

```
#define GETCOEF(
    x,
    y ) x += *x; y = x[-1]; x -= ABS(y); y=REDLENG(y)
```

Definition at line 46 of file [declare.h](#).

#### 4.19.2.8 GETSTOP

```
#define GETSTOP(
    x,
    y ) y=x+(*x)-1; y -= ABS(*y)-1
```

Definition at line 47 of file [declare.h](#).

#### 4.19.2.9 StuffAdd

```
#define StuffAdd(
    x,
    y ) ((x)<0?-1:1)*(y)+((y)<0?-1:1)*(x)
```

Definition at line 48 of file [declare.h](#).

#### 4.19.2.10 EXCHN

```
#define EXCHN(
    t1,
    t2,
    n ) { WORD a,i; for(i=0;i<n;i++){a=t1[i];t1[i]=t2[i];t2[i]=a;} }
```

Definition at line 50 of file [declare.h](#).

#### 4.19.2.11 EXCH

```
#define EXCH(
    x,
    y ) { WORD a = (x); (x) = (y); (y) = a; }
```

Definition at line 51 of file [declare.h](#).

#### 4.19.2.12 TOKENTOLINE

```
#define TOKENTOLINE(
    x,
    y )
```

**Value:**

```
if ( AC.OutputSpaces == NOSPACEFORMAT ) { \
    TokenToLine((UBYTE *) (y)); } else { TokenToLine((UBYTE *) (x)); }
```

Definition at line 53 of file [declare.h](#).

**4.19.2.13 UngetFromStream**

```
#define UngetFromStream(
    stream,
    c ) ((stream)->nextchar[(stream)->isnextchar++]=c)
```

Definition at line 56 of file [declare.h](#).

**4.19.2.14 AddLineFeed**

```
#define AddLineFeed(
    s,
    n ) { (s)[(n)++] = LINEFEED; }
```

Definition at line 60 of file [declare.h](#).

**4.19.2.15 TryRecover**

```
#define TryRecover(
    x ) Terminate(-1)
```

Definition at line 62 of file [declare.h](#).

**4.19.2.16 UngetChar**

```
#define UngetChar(
    c ) { pushbackchar = c; }
```

Definition at line 63 of file [declare.h](#).

**4.19.2.17 ParseNumber**

```
#define ParseNumber(
    x,
    s ) { (x)=0;while(*(s)>='0'&&*(s)<='9') (x)=10*(x)+*(s)++ - '0'; }
```

Definition at line 64 of file [declare.h](#).

**4.19.2.18 ParseSign**

```
#define ParseSign(
    sgn,
    s )
```

**Value:**

```
{ (sgn)=0;while(*(s)=='-'||*(s)=='+'){\
if ( *(s)++ == '-' ) sgn ^= 1;}}
```

Definition at line 65 of file [declare.h](#).

#### 4.19.2.19 ParseSignedNumber

```
#define ParseSignedNumber(  
    x,  
    s )
```

**Value:**

```
{ int sgn; ParseSign(sgn,s)\  
  ParseNumber(x,s) if ( sgn ) x = -x; }
```

Definition at line 67 of file [declare.h](#).

#### 4.19.2.20 NCOPY

```
#define NCOPY(  
    s,  
    t,  
    n ) { while ( (n)-- > 0 ) { *s++ = *t++; } }
```

Definition at line 71 of file [declare.h](#).

#### 4.19.2.21 NCOPYI

```
#define NCOPYI(

```
WORD * PasteTerm (
    PHEAD WORD number,
    WORD * accum,
    WORD * position,
    WORD times,
    WORD divby ) [extern]
```

Puts the term at position in the accumulator *accum* at position '*number*+1'. if *times* > 0 the coefficient of this term is multiplied by *times*/*divby*.

##### Parameters

|                 |                                                                                   |
|-----------------|-----------------------------------------------------------------------------------|
| <i>number</i>   | The number of term fragments in <i>accum</i> that should be skipped               |
| <i>accum</i>    | The accumulator of term fragments                                                 |
| <i>position</i> | A position in (typically) a compiler buffer from where a (piece of a) term comes. |
| <i>times</i>    | Multiply the result by this                                                       |
| <i>divby</i>    | Divide the result by this.                                                        |

This routine is typically used when we have to replace a (sub)expression pointer by a power of a (sub)expression. This uses mostly a binomial expansion and the new term is the old term multiplied one by one by terms of the new expression. The factors *times* and *divby* keep track of the binomial coefficient. Once this is complete, the routine *FiniTerm* will make the contents of the accumulator into a proper term that still needs to be normalized.

#### 4.19.4.12 AddCoef()

```

WORD AddCoef (
    PHEAD WORD ** ps1,
    WORD ** ps2 ) [extern]

```

Adds the coefficients of the terms \*ps1 and \*ps2. The problem comes when there is not enough space for a new longer coefficient. First a local solution is tried. If this is not successful we need to move terms around. The possibility of a garbage collection should not be ignored, as avoiding this costs very much extra space which is nearly wasted otherwise.

If the return value is zero the terms cancelled.

The resulting term is left in \*ps1.

#### 4.19.4.15 AddPoly()

```
WORD AddPoly (
    PHEAD WORD ** ps1,
    WORD ** ps2 ) [extern]
```

Routine should be called when  $S \rightarrow \text{PolyWise} \neq 0$ . It points then to the position of  $\text{AR.PolyFun}$  in both terms.

We add the contents of the arguments of the two polynomials. Special attention has to be given to special arguments. We have to reserve a space equal to the size of one term + the size of the argument of the other. The addition has to be done in this routine because not all objects are reentrant.

Newer addition (12-nov-2007). The PolyFun can have two arguments. In that case  $S \rightarrow \text{PolyFlag}$  is 2 and we have to call the routine for adding rational polynomials. We have to be rather careful what happens with: The location of the output The order of the terms in the arguments At first we allow only univariate polynomials in the PolyFun. This restriction will be lifted a.s.a.p.

## Parameters

|            |                                              |
|------------|----------------------------------------------|
| <i>ps1</i> | A pointer to the position of the first term  |
| <i>ps2</i> | A pointer to the position of the second term |

## Returns

If zero the terms cancel. Otherwise the new term is in \*ps1.

#### 4.19.4.33 Compare1()

```
WORD Compare1 (
    PHEAD WORD * term1,

    WORD level ) [extern]
```

Compares two terms. The answer is: 0 equal ( with exception of the coefficient if level == 0. ) >0 term1 comes first.  
 <0 term2 comes first. Some special precautions may be needed to keep the CompCoef routine from generating overflows, although this is very unlikely in subterms. This routine should not return an error condition.

Originally this routine was called Compare. With the treatment of special polynomials with terms that contain only symbols and the need for extreme speed for the polynomial routines we made a special compare routine and now we store the address of the current compare routine in AR.CompareRoutine and have a macro Compare which makes all existing code work properly and we can just replace the routine on a thread by thread basis (each thread has its own AR struct).

## Parameters

|              |                                                 |

| <i>term2</i> | Second input term                               |
| <i>level</i> | The sorting level (may influence on the result) |

## Returns

0 equal ( with exception of the coefficient if level == 0. ) >0 term1 comes first. <0 term2 comes first.

When there are floating point numbers active (float\_ = FLOATFUN) the presence of one or more float\_ functions is returned in AT.SortFloatMode: 0: no float\_ 1: float\_ in term1 only 2: float\_ in term2 only 3: float\_ in both terms

Special attention goes to having it thread-safe We have to lock positioning the file and reading it in a thread specific buffer.

| <i>term</i>  | The term that must be multiplied by the contents of the current bracket                            |
| <i>level</i> | The compiler level. This is needed because after multiplying term by term we call Generator again. |

Routine gets one power of an expression in the scratch system. If there are more powers needed there will be a recursion.

No attempt is made to use binomials because we have no information about commuting properties.

There is a searching for the contents of brackets if needed. This searching may be rather slow because of the single links.

**Parameters**

|               |                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <i>term</i>   | is the term we are adding to.                                                                                                        |
| <i>power</i>  | is the power of the expression that we need.                                                                                         |
| <i>nexp</i>   | is the number of the expression.                                                                                                     |
| <i>accum</i>  | is the accumulator of terms. It accepts the termfragments that are made into a proper term in FiniTerm                               |
| <i>aa</i>     | points to the start of the entire accumulator. In *aa we store the number of term fragments that are in the accumulator.             |
| <i>level</i>  | is the current depth in the tree of statements. It is needed to continue to the next operation/substitution with each generated term |
| <i>freeze</i> | is the pointer to the bracket information that should be matched.                                                                    |

#### 4.19.4.84 EndSort()

```
LONG EndSort (
    PHEAD WORD * buffer,
    int par ) [extern]
```

Finishes a sort. At AR.sLevel == 0 the output is to the regular output stream. When AR.sLevel > 0, the parameter par determines the actual output. The AR.sLevel will be popped. All ongoing stages are finished and if the sortfile is open it is closed. The statistics are printed when AR.sLevel == 0 par == 0 [Output](#) to the buffer. par == 1 Sort for function arguments. The output will be copied into the buffer. It is assumed that this is in the WorkSpace. par == 2 Sort for \$-variable. We return the address of the buffer that contains the output in buffer (treated like WORD \*\*). We first catch the output in a file (unless we can intercept things after the small buffer has been sorted) Then we read from the file into a buffer. Only when par == 0 data compression can be attempted at AT.SS==AT.S0.

##### Parameters

|---------------|-------------------------------|
| <i>buffer</i> | buffer for output when needed |
| <i>par</i>    | See above                     |

##### Returns

Garbage collection that takes place when the small extension is full and we need to place more terms there. When this is the case there are many holes in the small buffer and the whole can be compactified. The major complication is the buffer for SplitMerge. There are two options for temporary memory: 1: find some buffer that has enough space (maybe in the large buffer). 2: allocate a buffer. Give it back afterwards of course. If the small extension is properly dimensioned this routine should be called very rarely. Most of the time it will be called when the polyfun or polyratfun is active.

```
WORD Generator (
    PHEAD WORD * term,

## Parameters

|              |                                                        |
|--------------|--------------------------------------------------------|
| <i>term</i>  | the input term. may be overwritten                     |
| <i>level</i> | the level in the compiler buffer (number of statement) |

## Returns

Normal conventions (OK = 0).

The routine looks first whether there are unsubstituted (sub)expressions. If so, one of them gets inserted term by term and the new term is used in a renewed call to Generator. If there are no (sub)expressions, the term is normalized, the compiler level is raised (next statement) and the program looks what type of statement this is. If this is a special statement it is either treated on the spot or the appropriate routine is called. If it is a substitution, the pattern matcher is called (TestMatch) which tells whether there was a match. If so we need to call TestSub again to test for (sub)expressions. If we run out of levels, the term receives a final treatment for modulus calculus and/or brackets and is then sent off to the sorting routines.

```

Puts the terms 'term' and 'position' together into a single legal term in termout. replac is the number of the subexpression that should be replaced. It must be a positive term. When action is needed in the argument of a function all terms in that argument are dealt with recursively. The subexpression is sorted. Only one subexpression is done at a time this way.

#### 4.19.4.134 MergePatches()

```
WORD MergePatches (
    WORD par ) [extern]
```

The general merge routine. Can be used for the large buffer and the file merging. The array S->Patches tells where the patches start S->pStop tells where they end (has to be computed first). The end of a 'line to be merged' is indicated by a zero. If the end is reached without running into a zero or a term runs over the boundary of a patch it is a file merging operation and a new piece from the file is read in.

## 4.19.4.157 PrepPoly()

```
WORD PrepPoly (
    PHEAD WORD * term,
    WORD par ) [extern]
```

Routine checks whether the count of function AR.PolyFun is zero or one. If it is one and it has one scalarlike argument the coefficient of the term is pulled inside the argument. If the count is zero a new function is made with the coefficient as its only argument. The function should be placed at its proper position.

When this function is active it places the PolyFun as last object before the coefficient. This is needed because otherwise the compress algorithm has problems in MergePatches.

The bracket routine should also place the PolyFun at a comparable spot. The compression should then stop at the PolyFun. It doesn't really have to stop when writing the final result but this may be too complicated.

The parameter `par` tells whether we are at groundlevel or inside a function or dollar variable.

Here is the call graph for this function:

#### 4.19.4.158 Processor()

```
WORD Processor (
    void ) [extern]
```

This is the central processor. It accepts a stream of Expressions which is accessed by calls to `GetTerm`. The expressions reside either in `AR.infile` or `AR.hidefile`. The definitions of an expression are seen as an id-statement, so the primary Expressions should be written to the system of scratch files as single terms with an expression pointer. Each expression is terminated with a zero and the whole is terminated by two zeroes.

The routine `DoExecute` should determine whether results are to be printed, should revert the scratch I/O directions etc. In principle it is `DoExecute` that calls `Processor`.

#### Returns

if everything OK: 0. Otherwise error. The preprocessor may continue with compilation though. Really fatal errors should return on the spot by calling `Terminate`.

```

Reads a new patch from position in file handle. It is put at buffer, anything after take is moved forward. This would be part of a term that hasn't been used yet. Because of this there should be some space before the start of the buffer

## Parameters

Routine writes one term to file handle at position. It returns the new value of the position.

NOTE: For 'final output' we may have to index the brackets. See the struct BRACKETINDEX. We should maintain:  
 1: a list with brackets array with the brackets  
 2: a list of objects of type BRACKETINDEX. It contains array with either pointers or offsets to the list of brackets. starting positions in the file. The index may be tied to a maximum size. In that case we may have to prune the list occasionally.

## Parameters

|                 |                                                           |

```

Computes power  $x^n$  and caches the value

### 4.19.5 Description

Calculates the power  $x^n$  and stores the results for caching purposes. The pointer *c* (i.e., the pointer, and not what it points to) is overwritten. What it points to should not be overwritten in the calling function.

### 4.19.6 Notes

- Caching is done in `AT.small_power[]`. This array is extended if necessary.

```

Input m1 and m2, which are relative prime. determines  $a*m1+b*m2 = 1$  (and 1 is the gcd of m1 and m2) then  $a*m1 = 1 \bmod m2$  and hence  $im1 = a$ . and  $b*m2 = 1 \bmod m1$  and hence  $im2 = b$ . Set  $m1 = 0*m1+1*m2 = a1*m1+b1*m2$   
 $m2 = 1*m1+0*m2 = a2*m1+b2*m2$  If everything is OK, the return value is zero

#### 4.19.6.25 SplitMerge()

```
LONG SplitMerge (
    PHEAD WORD ** Pointer,
    LONG number ) [extern]
```

Algorithm by J.A.M.Vermaseren (31-7-1988)

Note that AN.SplitScratch and AN.InScratch are used also in GarbHand

Merge sort in memory. The input is an array of pointers. Sorting is done recursively by dividing the array in two equal parts and calling SplitMerge for each. When the parts are small enough we can do the compare and take the appropriate action. An addition is that we look for 'runs'. Sequences that are already ordered. This happens a lot when there is very little action in a module. This made FORM faster by a few percent.

##### Parameters

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>Pointer</i> | The array of pointers to the terms to be sorted. |
| <i>number</i>  | The number of pointers in Pointer.               |

The terms are supposed to be sitting in the small buffer and there is supposed to be an extension to this buffer for when there are two terms that should be added and the result takes more space than each of the original terms. The notation guarantees that the result never needs more space than the sum of the spaces of the original terms.

WORD TestMatch (

This routine governs the pattern matching. If it decides that a substitution should be made, this can be either the insertion of a right hand side (C->rhs) or the automatic generation of terms as a result of an operation (like trace). The object to be replaced is removed from term and a subexpression pointer is inserted. If the substitution is made more than once there can be more subexpression pointers. Its number is positive as it corresponds to the level at which the C->rhs can be found in the compiler output. The subexpression pointer contains the wildcard substitution information. The power is found in \*AT.TMout. For operations the subexpression pointer is negative and corresponds to an address in the array AT.TMout. In this array are then the instructions for the routine to be called and its number in the array 'Operations' The format is here: length,functionnumber,length-2 parameters

There is a certain complexity wrt repeat levels. Another complication is the poking of the wildcard values in the subexpression prototype in the compiler buffer. This was how things were done in the past with sequential FORM, but with the advent of TFORM this cannot be maintained. Now, for TFORM we make a copy of it. 7-may-2008 (JV): We cannot yet guarantee that this has been done 100% correctly. There are errors that occur in TFORM only and that may indicate problems.

## Parameters

|              |                                                                                                                                                                                                                    |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>name</i>  | Character string with the variable name.                                                                                                                                                                           |
| <i>value</i> | Character string with a possible value. Special case: if this argument is zero, then we have no value. Note: This is different from having an empty argument! This should only occur when the name starts with a ? |
| <i>args</i>  | Character string with possible arguments.                                                                                                                                                                          |

Preprocessor assignment. Possible arguments and values are treated and the new preprocessor variable is put into the name administration.

##### Parameters

|             |                                                                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>s</i>    | Pointer to the character string following the preprocessor command.                                                                                 |
| <i>mode</i> | Bitmask. 0-bit clear: always create a new name entry, 0-bit set: try to redefine an existing name, 1-bit set: ignore preprocessor if/switch status. |

##### Returns

zero: no errors, negative number: errors.

**4.19.6.307 ComPress()**

```
LONG ComPress (
    WORD ** ss,
    LONG * n ) [extern]
```

Gets a list of pointers to terms and compresses the terms. In *n* it collects the number of terms and the return value of the function is the space that is occupied.

We have to pay some special attention to the compression of terms with a PolyFun. This PolyFun should occur only straight before the coefficient, so we can use the same trick as for the coefficient to sabotage compression of this object (Replace in the history the function pointer by zero. This is safe, because terms that would be identical otherwise would have been added).

**Parameters**

|           |                                              |
|-----------|----------------------------------------------|
| <i>ss</i> | Array of pointers to terms to be compressed. |
| <i>n</i>  | Number of pointers in <i>ss</i> .            |

**4.19.6.333 TakeArgContent()**

```
WORD * TakeArgContent (
    PHEAD WORD * argin,
    WORD * argout ) [extern]
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. The common pieces are put in argout as a sequence of arguments. The part with the multiple terms that are now relative prime is put in argfree which is allocated via TermMalloc and is given as the return value. The difference with the old code is that negative powers are always removed. Hence it is as in MakeInteger in which only numerators will be left: now only zero or positive powers will be remaining.

#### 4.19.6.334 MakeInteger()

```
WORD * MakeInteger (
    PHEAD WORD * argin,
    WORD * argout,
    WORD * argfree ) [extern]
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in argin. The number that comes out should go to argout. The new pointer in the argout buffer is the return value. The normalized argument is in argfree.

#### 4.19.6.335 MakeMod()

```
WORD * MakeMod (
    PHEAD WORD * argin,
    WORD * argout,

Similar to MakeInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

#### 4.19.6.336 FindArg()

```
WORD FindArg (  
    PHEAD WORD * a ) [extern]
```

Looks the argument up in the (workers) table. If it is found the number in the table is returned (plus one to make it positive). If it is not found we look in the compiler provided table. If it is found - the number in the table is returned (minus one to make it negative). If in neither table we return zero.

```
WORD InsertArg (  
    PHEAD WORD * argin,  
    WORD * argout,

```

Inserts the argument into the (workers) table. If the table is too full we eliminate half of it. The eliminated elements are the ones that have not been used most recently, weighted by their total use and age(?). If par == 0 it inserts in the regular factorization cache If par == 1 it inserts in the cache defined with the FactorCache statement

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in bufin. The number that comes out is the return value. The normalized argument is in bufout.

Similar to MakeDollarInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

#### 4.19.6.573 Optimize()

```
int Optimize (
    WORD exprnr,
    int do_print ) [extern]
```

Optimization of expression

#### 4.19.7 Description

This method takes an input expression and generates optimized code to calculate its value. The following methods are called to do so:

- (1) `get_expression` : to read to expression
- (2) `get_brackets` : find brackets for simultaneous optimization
- (3) `occurrence_order` or `find_Horner_MCTS` : to determine (the) Horner scheme(s) to use; this depends on `AO.optimize.horner`
- (4) `optimize_expression_given_Horner` : to do the optimizations for each Horner scheme; this method does either CSE or greedy optimizations dependings on `AO.optimize.method`
- (5) `generate_output` : to format the output in Form notation and store it in a buffer
- (6a) `optimize_print_code` : to print the expression (for "Print") or (6b) `generate_expression` : to modify the expression (for "#Optimize")

On ParFORM, all the processes must call this function at the same time. Then

- (1) Because only the master can access to the expression to be optimized, the master broadcast the expression to all the slaves after reading the expression (`PF_get_expression`).
- (2) `get_brackets` reads `optimize_expr` as the input and it works also on the slaves. We leave it although the bracket information is not needed on the slaves (used in (5) on the master).
- (3) and (4) `find_Horner_MCTS` and `optimize_expression_given_Horner` are parallelized.
- (5), (6a) and (6b) are needed only on the master.

#### 4.19.7.1 ClearOptimize()

```
int ClearOptimize (
    void ) [extern]
```

Optimization of expression

#### 4.19.8 Description

Clears the buffers that were used for optimization output. Clears the expression from the buffers (marks it to be dropped). Note: we need to use the expression by its name, because numbers may change if we drop other expressions between when we do the optimizations and clear the results (in [execute.c](#)). Also this is not 100% safe, because we could overwrite the optimized expression. But that can be done only in a Local or Global statement and hence we only have to test there that we might have to call ClearOptimize first. (in file [comexpr.c](#))

**4.19.8.21 EvalDoLoopArg()**

```
WORD EvalDoLoopArg (
    PHEAD WORD * arg,
    WORD par ) [extern]
```

Evaluates one argument of a do loop. Such an argument is constructed from SNUMBERS DOLLAREXPRES-  
SIONs and possibly DOLLAREXPR2s which indicate factors of the preceding dollar. Hence we have SNUM-  
BER,num DOLLAREXPRESSSION,numdollar DOLLAREXPRESSSION,numdollar,DOLLAREXPR2,numfactor DOL-  
LAREXPRESSSION,numdollar,DOLLAREXPR2,numfactor,DOLLAREXPR2,numfactor etc. Because we have a do-  
loop at every stage we should have a number. The notation in DOLLAREXPR2 is that  $\geq 0$  is number of yet another  
dollar and  $< 0$  is  $-n-1$  with  $n$  the array element or zero. The return value is the (short) number. The routine works its  
way through the list in a recursive manner.

##### Parameters

|     |             |                                                                                                            |
|-----|-------------|------------------------------------------------------------------------------------------------------------|
| out | <i>term</i> | Pointer to the buffer where the term should be written.                                                    |
| in  | <i>num</i>  | The expression number from which to get the term.                                                          |
| in  | <i>pre</i>  | Denotes a pre-processor call (1) or not (0). Used to determine the correct source file for the expression. |

**4.19.8.119 CompareSymbols()**

```
WORD CompareSymbols (
    PHEAD WORD * term1,
    WORD * term2,
    WORD par ) [extern]
```

Compares the terms, based on the value of AN.polysortflag. If term1 < term2 the return value is -1 If term1 > term2 the return value is 1 If term1 = term2 the return value is 0 The coefficients may differ. The terms contain only a single subterm of type SYMBOL. If AN.polysortflag = 0 it is a 'regular' compare. If AN.polysortflag = 1 the sum of the powers is more important par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in [sort.c](#)

#### 4.19.8.120 CompareHSymbols()

```
WORD CompareHSymbols (

Compares terms that can have only SYMBOL and HAAKJE subterms. If  $term1 < term2$  the return value is -1 If  $term1 > term2$  the return value is 1 If  $term1 = term2$  the return value is 0 par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in [sort.c](#)

Definition at line [3114](#) of file [sort.c](#).

#### 4.19.8.121 NextPrime()

```
WORD NextPrime (
    PHEAD WORD num ) [extern]
```

Gives the next prime number in the list of prime numbers.

If the list isn't long enough we expand it. For ease in ParForm and because these lists shouldn't be very big we let each worker keep its own list.

The list is cut off at MAXPOWER, because we don't want to get into trouble that the power of a variable gets larger than the prime number.

**4.19.8.128 ReadSaveHeader()**

```
WORD ReadSaveHeader (
    void ) [extern]
```

Reads the header in the save file and sets function pointers and flags according to the information found there. Must be called before any other ReadSave... function.

Currently works only for the exchange between 32bit and 64bit machines (WORD size must be 2 or 4 bytes)!

It is called by CoLoad().

**Returns**

= 0 everything okay, != 0 an error occurred

Definition at line 4065 of file [store.c](#).

**4.19.8.129 ReadSaveIndex()**

```
WORD ReadSaveIndex (
    FILEINDEX * fileind ) [extern]
```

Reads a FILEINDEX from the open save file specified by AO.SaveData.Handle. Translations for adjusting endianness and data sizes are done if necessary.

Depends on the assumption that sizeof(FILEINDEX) is the same everywhere. If FILEINDEX or INDEXENTRY change, then this functions has to be adjusted.

Called by CoLoad() and FindInIndex().

## Parameters

|                |                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------|

**4.19.8.130 ReadSaveExpression()**

```
WORD ReadSaveExpression (
    UBYTE * buffer,
    UBYTE * top,
    LONG * size,
    LONG * outsize ) [extern]
```

Reads an expression from the open file specified by AO.SaveData.Handle. The endianness flip and a resizing without renumbering is done in this function. Thereafter the buffer consists of chunks with a uniform maximal word size (32bit at the moment). The actual renumbering is then done by calling the function [ReadSaveTerm32\(\)](#). The result is returned in *buffer*.

If the translation at some point doesn't fit into the buffer anymore, the function returns and must be called again. In any case *size* returns the number of successfully read bytes, *outsize* returns the number of successfully written bytes, and the file will be positioned at the next byte after the successfully read data.

It is called by PutInStore().

## Parameters

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>buffer</i>  | output buffer, holds the (translated) expression |
| <i>top</i>     | end of buffer                                    |
| <i>size</i>    | number of read bytes                             |
| <i>outsize</i> | number of written bytes                          |

## Returns

= 0 everything okay, != 0 an error occurred

Definition at line 5146 of file [store.c](#).

#### 4.19.8.131 ReadSaveTerm32()

```

UBYTE * ReadSaveTerm32 (
    UBYTE * bin,
    UBYTE * binend,
    UBYTE ** bout,
    UBYTE * boutend,
    UBYTE * top,
    int terminbuf ) [extern]
  
```

Reads a single term from the given buffer at *bin* and write the translated term back to this buffer at *bout*.

[ReadSaveTerm32\(\)](#) is currently the only instantiation of a `ReadSaveTerm`-function. It only deals with data that already has the correct endianness and that is resized to 32bit words but without being renumbered or translated in any other way. It uses the compress buffer `AR.CompressBuffer`.

The function is reentrant in order to cope with nested function arguments. It is called by [ReadSaveExpression\(\)](#) and itself.

The *return value* indicates the position in the input buffer up to which the data has already been successfully processed. The parameter *bout* returns the corresponding position in the output buffer.

##### Parameters

#### 4.19.8.132 ReadSaveVariables()

```
WORD ReadSaveVariables (
    UBYTE * buffer,
    UBYTE * top,
    LONG * size,
    LONG * outsize,
    INDEXENTRY * ind,
    LONG * stage ) [extern]
```

Reads the variables from the open file specified by AO.SaveData.Handle. It reads the *\*size* bytes and writes them to the *\*buffer*. It is called by PutInStore().

If translation is necessary, the data might shrink or grow in size, then *\*size* is adjusted so that the reading and writing fits into the memory from the buffer to the top. The actual number of read bytes is returned in *\*size*, the number of written bytes is returned in *\*outsize*.

If the *\*size* is smaller than the actual size of the variables, this function will be called several times and needs to remember the current position in the variable structure. The parameter *stage* does this job. When [ReadSaveVariables\(\)](#) is called for the first time, this parameter should have the value -1.

The parameter *ind* is used to get the number of variables.

#### 4.19.8.138 DoRecovery()

```
int DoRecovery (
    int * moduletype ) [extern]
```

Reads from the recovery file and restores all necessary variables and states in FORM, so that the execution can recommence in `preprocessor()` as if no restart of FORM had occurred.

The recovery file is read into memory as a whole. The pointer `p` then points into this memory at the next non-processed data. The macros by which variables are restored, like `R_SET`, automatically increase `p` appropriately.

If something goes wrong, the function returns with a non-zero value.

Allocated memory that would be lost when overwriting the global structs with data from the file is freed first. A major part of the code deals with the restoration of pointers. The idiom we use is to memorize the original pointer value (`org`), allocate new memory and copy the data from the file into this memory, calculate the offset between the old pointer value and the new allocated memory position (`ofs`), and then correct all affected pointers (`+=ofs`).

We rely on the fact that several variables (especially in AM) are already assigned the correct values by the startup functions. That means, in principle, that a change in the setup files between snapshot creation and recovery will be noticed.

Converts a generic term to polynomial notation in which there are only symbols and brackets. During conversion there will be only symbols. Brackets are stripped. Objects that need 'translation' are put inside a special compiler buffer and represented by a symbol. The numbering of the extra symbols is down from the maximum. In principle there can be a problem when running into the already assigned ones. This uses the FindTree for searching in the global tree and then looks further in the AT.ebufnum. This allows fully parallel processing. Hence we need no locks. Cannot be used in the same module as ConvertToPoly.

**4.19.8.195 TakeSymbolContent()**

```
WORD * TakeSymbolContent (

```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. We allow only symbols as this code is used for the polyratfun only. We have a special routine, because the generic TakeContent does too much work and speed is at a premium here. Input: in is the input expression as a sequence of terms. **Output:** term: the content return value: the contentfree expression. it is in new allocation, made by TermMalloc. (should be in a TermMalloc space?)

#### 4.19.8.200 TakeContent()

```
WORD * TakeContent (
    PHEAD WORD * in,
    WORD * term ) [extern]
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. Here the input is a sequence of terms in 'in' and the answer is a content-free sequence of terms. This sequence has been allocated by the Malloc1 routine in a call to EndSort, unless the expression was already content-free. In that case the input pointer is returned. The content is returned in term. This is supposed to be a separate allocation, made by TermMalloc in the calling routine.

00042
00043     Syntax:
00044         Canonicalize,mainoption,...
00045     With the main options currently:
00046         Canonicalize,topology,vertexfunction,edgefunction,OutDollar,extraoptions;
00047         Canonicalize,polynomial,InDollar,set_or_setname_or_dollar,OutDollar,extraoptions;
00048     The vertex function needs to have the format (assume it is called vx):
00049         vx(p1,p2,-p3) or vx(-p1,p2,p3,-p4) etc.
00050     The external lines have a vertex with only one line.
00051     All momenta that form connections should be unique.
00052     In principle the - signs are not relevant for the topology, but they
00053     may exist already in the remaining part of the diagram. They are also
00054     part of the canonical form.
00055     The edge function can be used in different ways, depending on the options.
00056     The extraoption(s) should be nonnegative integers or $variables that evaluate
00057     into nonnegative integers (integers less than 2^31).
00058     The Indollar variable contains the polynomial to be canonicalized.
00059     The OutDollar variable should be the name of a $-variable (as in $out) which
00060     will be filled with a replace_ function. The canonicalization can then
00061     be executed in the whole term with the Multiply $out; command.
