4.91.1 Detailed Description

Contains the 'operations' These are the trace routines, the contractions of the Levi-Civita tensors and the tensor to vector/vector to tensor routines. The trace and contraction routines are done in a special way (see commentary with the FIXEDGLOBALS struct)

00389

```

```

00390      Takes the trace of a string of gamma matrices in 4 dimensions.
00391      There is no test for indices or vectors that are the same.
00392      The four dimensions refer to the contraction in the algebra:
00393      g_(i,a,b,c) = e_(a,b,c,d)*g_(i,5_,d) + g_(i,a)*d_(b,c)
00394                  - g_(i,b)*d_(a,c) + g_(i,c)*d_(a,b)
00395      This simplifies life very much and leads to shorter expressions
00396      than in the n dimensional case.
00397
00398      Parameters:
00399      number: the number of vectors/indices in inlist.
00400      inlist: the indices/vectors in the string.
00401      kron:   the output delta's.
00402      gamma5: the potential gamma5 in front.
00403      t:      the struct for scratch manipulations.
00404      stack:  the space to put all scratch arrays in.
00405
00406      The return value is zero if there are no more terms, 1 if a
00407      term was generated with a positive sign and -1 if a term was
00408      generated with a negative sign.
00409      The value of one is increased to two if the first 4 values
00410      in kron should be interpreted as a Levi-Civita tensor.
00411
00412      Note that kron should have more places reserved than the number
00413      of indices in inlist, because it will contain dummy indices
00414      temporarily. In principle there can be 'number*1/4' extra dummies.

00667     #] Trace4no :
00668     #[ Trace4 :          WORD Trace4(term,params,num,level)
00669
00670     Generates traces of the string of gamma matrices in 'instring'.
00671
00672     The difference with the routine tracen ( for n dimensions )
00673     lies in the treatment of gamma 5 and the specific form
00674     of the Chisholm identities. The identities used here are
00675     g(mu)*g(al)*...*g(an)*g(mu)=
00676     n=odd: -2*g(an)*...*g(al)      ( reversed order )
00677     n=even: 2*g(an)*g(al)*...*g(a(n-1))
00678             +2*g(a(n-1))*...*g(al)*g(an)
00679     There is a special case for n=2 : 4*d(al,a2)*gi
00680
00681     The main difference with the old fortran version lies in
00682     the recursion that is used here. That cleans up the variables
00683     very much.
00684
00685     The contents of the AT.TMout array are:
00686     length,type,gamma5,gamma's
00687
00688     The space for the vectors in t is at most 14 * number.
00689
00690     The condition params[5] == 0 corresponds to finding gamma6*gamma7
00691     during the pick up of the matrices.

00826 /*
00827 #] Trace4 :
00828 #[ Trace4Gen :          WORD Trace4Gen(t,number)
00829
00830 The recursive breakdown of a trace in 4 dimensions.
00831 We test first whether the trace has zero or two gamma's left.
00832 This case can be done quickly.
00833 Next we test whether we can eliminate adjacent objects that are
00834 the same.
00835 Then we test for Chisholm identities (I). First for identities
00836 with an odd number of gamma matrices (II), then for those with an
00837 even number of matrices (III). The special thing here is the demand
00838 that the contraction be between indices with 4 dimensions only.
00839 Then there is a scan for objects that are the same, not regarding
00840 their type (IV). This is exactly the same as in n dimensions.
00841 Finally we have a string left in which all objects are different (V).
00842 This case is treated by the routine Trace4no (no stands for no
00843 objects are the same).
00844
00845 In case I we have one d_ of which the result of the contraction
00846 has not yet been fixed.
00847 Case II gives just a reordering of the matrices and a factor -2.
00848 Case III gives two terms: one for the anti commutation, such that
00849 the number of intermediate matrices becomes odd and the other
00850 from the Chisholm rule for an odd number of matrices. Both have
00851 a factor 2.
00852 Case IV gives m+1 terms when m is the number of matrices inbetween.
00853 We take the shortest path. The sign alternates and all terms have
00854 a factor two, except for the last one.

4.93.1 Detailed Description

experimental routines for the optimization of FORTRAN or C output.

Definition in file [optimize.cc](#).

4.93.2 Function Documentation

4.93.2.1 print_instr()

```
void print_instr (
    const vector< WORD > & instr,
    WORD num )
```

Definition at line [179](#) of file [optimize.cc](#).

4.93.2.2 my_random_shuffle()

```
template<class RandomAccessIterator >
void my_random_shuffle (
    PHEAD RandomAccessIterator fr,
    RandomAccessIterator to )
```

Random shuffle

4.93.3 Description

Randomly permutes elements in the range [fr,to). Functionality is the same as C++'s "random_shuffle", but it uses Form's "wranf".

Definition at line [201](#) of file [optimize.cc](#).

Referenced by [find_Horner_MCTS\(\)](#).

4.93.3.1 `get_expression()`

```
LONG get_expression (
    int exprnr )
```

Get expression

4.93.4 Description

Reads an expression from the input file into a buffer (called `optimize_expr`). This buffer is used during the optimization process. Non-symbols are removed by `ConvertToPoly` and are put in temporary symbols.

The return value is the length of the expression in WORDs, or a negative number if it failed.

Definition at line 225 of file [optimize.cc](#).

References [EndSort\(\)](#), [LowerSortLevel\(\)](#), [NewSort\(\)](#), and [StoreTerm\(\)](#).

Referenced by [Optimize\(\)](#).

Here is the call graph for this function:

4.93.4.1 `get_brackets()`

```
vector< vector< WORD > > get_brackets ( )
```

Get brackets

4.93.5 Description

Checks whether the input expression (stored in `optimize_expr`) contains brackets. If so, this method replaces terms outside brackets by powers of `SEPERATESYMBOL` (equal brackets have equal powers) and the brackets are returned. If not, the result is empty.

Brackets are used for simultaneous optimization. The symbol `SEPERATESYMBOL` is always the first one used in a Horner scheme.

Definition at line 302 of file [optimize.cc](#).

Referenced by [Optimize\(\)](#).

4.93.5.1 `count_operators()` [1/2]

```
int count_operators (
    const WORD * expr,
    bool print = false )
```

Count operators

4.93.6 Description

Counts the number of operators in a Form-style expression.

Definition at line 422 of file [optimize.cc](#).

Referenced by [find_Horner_MCTS\(\)](#), [generate_instructions\(\)](#), [Optimize\(\)](#), [optimize_expression_given_Horner\(\)](#), and [optimize_greedy\(\)](#).

4.93.6.1 `count_operators()` [2/2]

```
int count_operators (
    const vector< WORD > & instr,
    bool print = false )
```

Count operators

4.93.7 Description

Counts the number of operators in a vector of instructions

Definition at line 476 of file [optimize.cc](#).

4.93.7.1 `occurrence_order()`

```
vector< WORD > occurrence_order (
    const WORD * expr,
    bool rev )
```

Occurrence order

4.93.8 Description

Extracts all variables from an expression and sorts them with most occurring first (or last, with `rev=true`)

Definition at line 519 of file [optimize.cc](#).

Referenced by [Optimize\(\)](#).

4.93.8.1 `getpower()`

```
WORD getpower (
    const WORD * term,
    int var,
    int pos )
```

Horner tree building

4.93.9 Description

Given a Form-style expression (in a buffer in memory), this builds an expression tree. The tree is determined by a multivariate Horner scheme, i.e., something of the form:

$$1+y+x*(2+y*(1+y)+x*(3-y*(...)))$$

The order of the variables is given to the method "Horner_tree", which rennumbers ad reorders the terms of the expression. Next, the recursive method "build_Horner_tree" does the actual tree construction.

The tree is represented in postfix notation. Tokens are of the following forms:

- SNUMBER tokenlength num den coefflength
- SYMBOL tokenlength variable power
- OPER_ADD or OPER_MUL

4.93.10 Note

Sets AN.poly_num_vars and allocates AN.poly_vars. The latter should be freed later. Get power of variable (helper function for build_Horner_tree)

4.93.11 Description

Returns the power of the variable "var", which is at position "pos" in this term, if it is present.

Definition at line 600 of file [optimize.cc](#).

Referenced by [build_Horner_tree\(\)](#).

4.93.11.1 `fixarg()`

```
void fixarg (
    UWORD * t,
    WORD & n )
```

Call GcdLong/DivLong with leading zeroes

4.93.12 Description

These method remove leading zeroes, so that GcdLong and DivLong can safely be called.

Definition at line 614 of file [optimize.cc](#).

4.93.12.1 GcdLong_fix_args()

```
void GcdLong_fix_args (
    PHEAD UWORD * a,
    WORD na,
    UWORD * b,
    WORD nb,
    UWORD * c,
    WORD * nc )
```

Definition at line 620 of file [optimize.cc](#).

4.93.12.2 DivLong_fix_args()

```
void DivLong_fix_args (
    UWORD * a,
    WORD na,
    UWORD * b,
    WORD nb,
    UWORD * c,
    WORD * nc,
    UWORD * d,
    WORD * nd )
```

Definition at line 626 of file [optimize.cc](#).

4.93.12.3 build_Horner_tree()

```
void build_Horner_tree (
    const WORD ** terms,
    int numterms,
    int var,
    int maxvar,
    int pos,
    vector< WORD > * res )
```

Build the Horner tree

4.93.13 Description

Constructs the Horner tree. The method processes one variable and continues recursively until the Horner scheme is completed.

"terms" is a pointer to the starts of the terms. "numterms" is the number of terms to be processed. "var" is the next variable to be processed (index between 0 and #maxvar) and "maxvar" is the last variable to be processed, so that partial Horner trees can also be constructed. "pos" is the position that the power of "var" should be in (one level further in the recursion, "pos" has increased by 0 or 1 depending on whether the previous power was 0 or not). The result is written at the pointer "res".

This method also factors out gcds of the coefficients. The result should end with "gcd OPER_MUL" at all times, so that one level higher gcds can be extracted again.

4.93.13.1 term_compare()

```

bool term_compare (
    const WORD * a,
    const WORD * b )
  
```

Term compare (helper function for Horner_tree)

4.93.14 Description

Compares two terms of the form "L SYM 4 x n coeff" or "L coeff". Lower powers of lower-indexed symbols come first. This is used to sort the terms in correct order.

Definition at line 852 of file [optimize.cc](#).

Referenced by [Horner_tree\(\)](#).

4.93.14.1 Horner_tree()

```
vector< WORD > Horner_tree (
    const WORD * expr,
    const vector< WORD > & order )
```

Prepare Horner tree building

4.93.15 Description

This method rennumbers the variables to 0...#vars-1 according to the specified order. Next, it stored pointer to individual terms and sorts the terms with higher power first. Then the sorted lists of power is used for the construction of the Horner tree.

Definition at line 873 of file [optimize.cc](#).

Definition at line 1070 of file [optimize.cc](#).

4.93.15.3 generate_instructions()

```
vector< WORD > generate_instructions (
    const vector< WORD > & tree,
    bool do_CSE )
```

Generate instructions

4.93.16 Description

Converts the expression tree to a list of instructions that directly translate to code. Instructions are of the form:

expr.nr operator length [operands]+ trailing.zero

The operands are of the form:

length [(EXTRA)SYMBOL length variable power] coeff

This method only generates binary operators. Merging is done later. The method also checks for common subexpressions and eliminates them and the flag "do_CSE" is set.

4.93.17 Implementation details

The map "ID" keeps track of which subexpressions already exist. The key is formatted as one of the following:

SYMBOL x n SNUMBER coeff OPERATOR LHS RHS

with LHS/RHS formatted as one of the following:

SNUMBER idx 0 (EXTRA)SYMBOL x n

ID[symbol] or ID[operator] equals a subexpression number. ID[coeff] equals the position of the number in the input.

The stack s is used to process the postfix expression tree. Three-word tokens of the form:

SNUMBER idx.of.coeff 0 SYMBOL x n EXTRASYMBOL x 1

are pushed onto it. Operators pop two operands and push the resulting expression.

(Extra)symbols are 1-indexed, because -X is also needed to represent -1 times this term.

There is currently a bug. The notation cannot tell if there is a single bracket and then ignores the bracket.

TODO: check if this method performs properly if do_CSE=false

4.93.18.1 merge_operators()

```
vector< WORD > merge_operators (
    const vector< WORD > & all_instr,
    bool move_coeff )
```

Merge operators

4.93.19 Description

The input instructions form a binary DAG. This method merges expressions like

$Z1 = a+b; Z2 = Z1+c;$

into

$Z2 = a+b+c;$

An instruction is merged iff it only has one parent and the operator equals its parent's operator.

This still leaves some freedom: where should the coefficients end up in cases as:

$Z1 = Z2 + x \Leftrightarrow Z1 = 2*Z2 + x \quad Z2 = 2*x*y \quad Z2 = x*y$

Both are relevant, e.g. for CSE of the form "2*x" and "2*Z2". The flag "move_coeff" moves coefficients from LHS-like expressions to RHS-like expressions.

Furthermore, this method removes empty equation ($Z1=0$), that are introduced by some "optimize_greedy" substitutions.

4.93.20 Implementation details

Expressions are mostly traversed via a stack, so that parents are evaluated before their children.

With "move_coeff" set coefficients are moved, but this leads to some tricky cases, e.g.

$$Z1 = Z2 + x \quad Z2 = 2*y$$

Here Z2 reduces to the trivial equation $Z2=y$, which should be eliminated. Here the array skip[i] comes in.

Furthermore in the case

$$Z1 = Z2 + x \quad Z2 = 2*Z3 \quad Z3 = x*Z4 \quad Z4 = y*z$$

after substituting $Z1 = 2*Z3 + x$, the parent expression for Z4 becomes Z3 instead of Z2. This is where renum_par[i] comes in.

Finally, once a coefficient has been moved, skip_coeff[i] is set and this coefficient is copied into the new expression anymore.

4.93.20.1 find_optimizations()

```
vector< optimization > find_optimizations (
    const vector< WORD > & instr )
```

Find optimizations

4.93.21 Description

This method find all optimization of the form described in "class Optimization". It process every equation, looking for possible optimizations and stores them in a fast-access data structure to count the total improvement of an optimization.

Definition at line 2697 of file [optimize.cc](#).

Referenced by [optimize_greedy\(\)](#).

4.93.21.1 do_optimization()

```
bool do_optimization (
    const optimization optim,
    vector< WORD > & instr,
    int newid )
```

Do optimization

4.93.22 Description

This method performs an optimization. It scans through the equations of "optim.eqnidxs" and looks in which this optimization can still be performed (due to other performed optimizations this isn't always the case). If possible, it substitutes the common subexpression by a new extra symbol numbered "newid". Finally, the new extrasymbol is defined accordingly.

Substitutions may lead to trivial equations of the form " $Z_i=Z_j$ ", but these are removed in the end of the method. The method returns whether the substitution has been done once or more (or not).

Definition at line 2930 of file [optimize.cc](#).

Referenced by [optimize_greedy\(\)](#).

4.93.22.1 partial_factorize()

```
int partial_factorize (
    vector< WORD > & instr,
    int n,
    int improve )
```

Partial factorization of instructions

4.93.23 Description

This method performs partial factorization of instructions. In particular the following instructions

$Z_1 = x*a*b$ $Z_2 = x*c*d*e$ $Z_3 = 2*x + Z_1 + Z_2 + \text{more}$

are replaced by

$Z_1 = a*b$ $Z_2 = c*d*e$ $Z_3 = Z_j + \text{more}$ $Z_i = 2 + Z_1 + Z_2$ $Z_j = x*Z_i$

Here it is necessary that no other equations refer to Z_1 and Z_2 . The generation of trivial instructions ($Z_i=Z_j$ or $Z_i=x$) is prevented.

Definition at line 3479 of file [optimize.cc](#).

Referenced by [optimize_greedy\(\)](#).

4.93.23.1 optimize_greedy()

```
vector< WORD > optimize_greedy (
    vector< WORD > instr,
    LONG time_limit )
```

Optimize instructions greedily

4.93.24 Description

This method optimizes an expression greedily. It calls "find_optimizations" to obtain candidates and performs the best one(s) by calling "do_optimization".

How many different optimization are done, before "find_optimization" is called again, is determined by the settings "greedyminnum" and "greedymaxperc".

During the optimization process, sequences of zeroes are introduced in the instructions, since moving all instructions when one gets optimized, is very costly. Therefore, in the end, the instructions are "compressed" again to remove these extra zeroes.

Definition at line 3773 of file [optimize.cc](#).

References [count_operators\(\)](#), [do_optimization\(\)](#), [find_optimizations\(\)](#), [partial_factorize\(\)](#), and [TimeWallClock\(\)](#).

Here is the call graph for this function:

4.93.24.1 recycle_variables()

```
vector< WORD > recycle_variables (
    const vector< WORD > & all_instr )
```

Recycle variables

4.93.25 Description

The current input uses many temporary variables. Many of them become obsolete at some point during the evaluation of the code, so can be recycled. This method rennumbers the temporary variables, so that they are recycled. Furthermore, the input is order in depth-first order, so that the instructions can be performed consecutively.

4.93.26 Implementation details

First, for each subDAG, an estimate for the number of variables needed is made. This is done by the following recursive formula:

$$\#vars(x) = \max(\#vars(ch_i(x)) + i),$$

with $ch_i(x)$ the i -th child of x , where the childs are ordered w.r.t. $\#vars(ch_i)$. This formula is exact if the input forms a tree, and otherwise gives a reasonable estimate.

Then, the instructions are reordered in a depth-first order with childs ordered w.r.t. $\#vars$. Next, the times that variables become obsolete are found. Each LHS of an instruction is renumbered to the lowest-numbered temporary variable that is available at that time.

4.93.26.1 optimize_expression_given_Horner()

```
void optimize_expression_given_Horner ( )
```

Optimize expression given a Horner scheme

4.93.27 Description

This method picks one Horner scheme from the list of best Horner schemes, applies this scheme to the expression and then, depending on `optimize.settings`, does a common subexpression elimination (CSE) or performs greedy optimizations.

CSE is fast, while greedy might be slow. CSE followed by greedy is faster than greedy alone, but typically results in slightly worse code (not proven; just observed). eventually do greedy optimizations

    int print_expr )
```

Print optimized code

4.93.30 Description

This method prints the optimized code via "PrintExtraSymbol". Depending on the flag, the original expression is printed (for "Print") or not (for "#Optimize / #write "O").

Definition at line [4524](#) of file [optimize.cc](#).

Referenced by [Optimize\(\)](#).

4.93.30.1 Optimize()

```
int Optimize (
    WORD exprnr,
    int do_print )
```

Optimization of expression

4.93.31 Description

This method takes an input expression and generates optimized code to calculate its value. The following methods are called to do so:

- (1) `get_expression` : to read to expression
- (2) `get_brackets` : find brackets for simultaneous optimization
- (3) `occurrence_order` or `find_Horner_MCTS` : to determine (the) Horner scheme(s) to use; this depends on `AO.optimize.horner`
- (4) `optimize_expression_given_Horner` : to do the optimizations for each Horner scheme; this method does either CSE or greedy optimizations dependings on `AO.optimize.method`
- (5) `generate_output` : to format the output in Form notation and store it in a buffer
- (6a) `optimize_print_code` : to print the expression (for "Print") or (6b) `generate_expression` : to modify the expression (for "#Optimize")

On ParFORM, all the processes must call this function at the same time. Then

- (1) Because only the master can access to the expression to be optimized, the master broadcast the expression to all the slaves after reading the expression (`PF_get_expression`).
- (2) `get_brackets` reads `optimize_expr` as the input and it works also on the slaves. We leave it although the bracket information is not needed on the slaves (used in (5) on the master).
- (3) and (4) `find_Horner_MCTS` and `optimize_expression_given_Horner` are parallelized.
- (5), (6a) and (6b) are needed only on the master.

4.93.31.1 ClearOptimize()

```
int ClearOptimize (
    void )
```

Optimization of expression

4.93.32 Description

Clears the buffers that were used for optimization output. Clears the expression from the buffers (marks it to be dropped). Note: we need to use the expression by its name, because numbers may change if we drop other expressions between when we do the optimizations and clear the results (in [execute.c](#)). Also this is not 100% safe, because we could overwrite the optimized expression. But that can be done only in a Local or Global statement and hence we only have to test there that we might have to call ClearOptimize first. (in file [comexpr.c](#))

4.95.1 Detailed Description

Message passing library independent functions of parform

This file contains functions needed for the parallel version of form3 these functions need no real link to the message passing libraries, they only need some interface dependent preprocessor definitions (check [parallel.h](#)). So there still need two different objectfiles to be compiled for mpi and pvm!

Definition in file [parallel.c](#).

4.95.2 Macro Definition Documentation

4.95.2.1 PRINTFBUF

```
#define PRINTFBUF(
    TEXT,
    TERM,
    SIZE ) {}
```

Definition at line 117 of file [parallel.c](#).

4.95.2.2 SWAP

```
#define SWAP(
    x,
    y )
```

Value:

```
do { \
    char swap_tmp__[sizeof(x) == sizeof(y) ? (int)sizeof(x) : -1]; \
    memcpy(swap_tmp__, &y, sizeof(x)); \
    memcpy(&y, &x, sizeof(x)); \
    memcpy(&x, swap_tmp__, sizeof(x)); \
} while (0)
```

Swaps the variables *x* and *y*. If `sizeof(x) != sizeof(y)` then a compilation error will occur. A set of `memcpy` calls with constant sizes is expected to be inlined by the optimisation.

Definition at line 124 of file [parallel.c](#).

4.95.2.3 PACK_LONG

```
#define PACK_LONG(
    p,
    n )
```

Value:

```
do { \
    *p)++ = (UWORD)((ULONG)(n) & (ULONG)WORDMASK); \
    *p)++ = (UWORD)((ULONG)(n) >> BITSINWORD) & (ULONG)WORDMASK); \
} while (0)
```

Packs a LONG value *n* to a WORD buffer *p*.

Definition at line 135 of file [parallel.c](#).

4.95.2.4 UNPACK_LONG

```
#define UNPACK_LONG(
    p,
    n )
```

Value:

```
do { \
    (n) = (LONG)((((ULONG)(p)[1] & (ULONG)WORDMASK) << BITSINWORD) | ((ULONG)(p)[0] & (ULONG)WORDMASK)); \
    (p) += 2; \
} while (0)
```

Unpacks a LONG value *n* from a WORD buffer *p*.

Definition at line 144 of file [parallel.c](#).

4.95.2.5 CHECK

```
#define CHECK(
    condition ) _CHECK(condition, __FILE__, __LINE__)
```

A simple check for unrecoverable errors.

Definition at line 153 of file [parallel.c](#).

4.95.2.6 _CHECK

```
#define _CHECK(  
    condition,  
    file,  
    line ) __CHECK(condition, file, line)
```

Definition at line 154 of file [parallel.c](#).

4.95.2.7 __CHECK

```
#define __CHECK(  
    condition,  
    file,  
    line )
```

Value:

```
do { \  
    if ( !(condition) ) { \  
        Error0("Fatal error at " file ":" #line); \  
        Terminate(-1); \  
    } \  
} while (0)
```

Definition at line 155 of file [parallel.c](#).

4.95.2.8 DBGOUT

```
#define DBGOUT(  
    lv1,  
    lv2,  
    a ) do { if ( lv1 >= lv2 ) { printf a; fflush(stdout); } } while (0)
```

Definition at line 166 of file [parallel.c](#).

4.95.2.9 DBGOUT_NINTERMS

```
#define DBGOUT_NINTERMS(  
    lv,  
    a )
```

Definition at line 169 of file [parallel.c](#).

4.95.2.10 PF_STATS_SIZE

```
#define PF_STATS_SIZE 5
```

Definition at line 178 of file [parallel.c](#).

4.95.2.11 PF_SNDFILEBUFSIZE

```
#define PF_SNDFILEBUFSIZE 4096
```

Definition at line 4211 of file [parallel.c](#).

4.95.2.12 recvBuffer

```
#define recvBuffer logBuffer /* (master) The buffer for receiving messages. */
```

Definition at line 4319 of file [parallel.c](#).

4.95.3 Typedef Documentation

4.95.3.1 NODE

```
typedef struct NoDe NODE
```

A node for the tree of losers in the final sorting on the master.

4.95.4 Function Documentation

4.95.4.1 PF_RealTime()

```
LONG PF_RealTime (  
    int i )
```

Returns the realtime in 1/100 sec. as a LONG.

Parameters

<i>i</i>	the timer will be reset if <code>i == 0</code> .
----------	--

Returns

the real elapsed time in 1/100 second.

Definition at line 101 of file [mpi.c](#).

Referenced by [PF_Init\(\)](#).

4.95.4.2 PF_LibInit()

```
int PF_LibInit (  
    int * argcp,  
    char *** argvp )
```

Performs all library dependent initializations.

Parameters

<i>argcp</i>	pointer to the number of arguments.
<i>argvp</i>	pointer to the arguments.

Returns

0 if OK, nonzero on error.

Definition at line 123 of file [mpi.c](#).

Referenced by [PF_Init\(\)](#).

4.95.4.3 PF_LibTerminate()

```
int PF_LibTerminate (
    int error )
```

Exits mpi, when there is an error either indicated or happening, returnvalue is 1, else returnvalue is 0.

Parameters

<i>error</i>	an error code.
--------------	----------------

Returns

0 if OK, nonzero on error.

Definition at line 209 of file [mpi.c](#).

Referenced by [PF_Terminate\(\)](#).

4.95.4.4 PF_Probe()

```
int PF_Probe (
    int * src )
```

Probes the next incoming message. If `src == PF_ANY_SOURCE` this operation is blocking, otherwise nonblocking.

Parameters

<i>in, out</i>	<i>src</i>	the source process number. In output, the process number of actual found source.
----------------	------------	--

Returns

the tag value of the next incoming message if found, 0 if a nonblocking probe (input `src != PF_ANY_SOURCE`) did not find any messages. A negative returned value indicates an error.

Definition at line 230 of file [mpi.c](#).

4.95.4.5 PF_RecvWbuf()

```
int PF_RecvWbuf (
    WORD * b,
    LONG * s,
    int * src )
```

Blocking receive of a WORD buffer.

Parameters

out	<i>b</i>	the buffer to store the received data.
in, out	<i>s</i>	the size of the buffer. The output value is the actual size of the received data.
in, out	<i>src</i>	the source process number. The output value is the process number of actual source.

Returns

the received message tag. A negative value indicates an error.

Definition at line 337 of file [mpi.c](#).

4.95.4.6 PF_IRecvRbuf()

```
int PF_IRecvRbuf (
    PF_BUFFER * r,
    int bn,
    int from )
```

Posts nonblocking receive for the active receive buffer. The buffer is filled from full to stop.

Parameters

<i>r</i>	the PF_BUFFER struct for the nonblocking receive.
<i>bn</i>	the index of the cyclic buffer.
<i>from</i>	the source process number.

Returns

0 if OK, nonzero on error.

Definition at line 366 of file [mpi.c](#).

4.95.4.7 PF_WaitRbuf()

```
int PF_WaitRbuf (
    PF_BUFFER * r,
    int bn,
    LONG * size )
```

Waits for the buffer *bn* to finish a pending nonblocking receive. It returns the received tag and in **size* the number of field received. If the receive is already finished, just return the flag and size, else wait for it to finish, but also check for other pending receives.

Parameters

	<i>r</i>	the PF_BUFFER struct for the pending nonblocking receive.
	<i>bn</i>	the index of the cyclic buffer.
out	<i>size</i>	the actual size of received data.

Returns

the received message tag. A negative value indicates an error.

Definition at line [400](#) of file [mpi.c](#).

4.95.4.8 PF_RawSend()

```
int PF_RawSend (
    int dest,
    void * buf,
    LONG l,
    int tag )
```

Sends *l* bytes from *buf* to *dest*. Returns 0 on success, or -1.

Parameters

<i>dest</i>	the destination process number.
<i>buf</i>	the send buffer.
<i>l</i>	the size of data in the send buffer in bytes.
<i>tag</i>	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line [463](#) of file [mpi.c](#).

Referenced by [PF_MUnlock\(\)](#), and [PF_SendFile\(\)](#).

4.95.4.9 PF_RawRecv()

```
LONG PF_RawRecv (
    int * src,
    void * buf,
    LONG thesize,
    int * tag )
```

Receives not more than *thesize* bytes from *src*, returns the actual number of received bytes, or -1 on failure.

Parameters

in, out	<i>src</i>	the source process number. In output, that of the actual received message.
out	<i>buf</i>	the receive buffer.
	<i>thesize</i>	the size of the receive buffer in bytes.
out	<i>tag</i>	the message tag of the actual received message.

Returns

the actual sizeof received data in bytes, or -1 on failure.

Definition at line 484 of file [mpi.c](#).

Referenced by [PF_RecvFile\(\)](#).

4.95.4.10 PF_RawProbe()

```
int PF_RawProbe (
    int * src,
    int * tag,
    int * bytesize )
```

Probes an incoming message.

Parameters

in, out	<i>src</i>	the source process number. In output, that of the actual received message.
in, out	<i>tag</i>	the message tag. In output, that of the actual received message.
out	<i>bytesize</i>	the size of incoming data in bytes.

Returns

0 if OK, nonzero on error.

Definition at line 508 of file [mpi.c](#).

4.95.4.11 PF_EndSort()

```
int PF_EndSort (
    void )
```

Finishes a master sorting with collecting terms from slaves. Called by [EndSort\(\)](#).

If this is not the masterprocess, just initialize the sendbuffers and return 0, else [PF_EndSort\(\)](#) sends the rest of the terms in the sendbuffer to the next slave and a dummy message to all slaves with tag PF_ENDSORT_MSGTAG. Then it receives the sorted terms, sorts them using a recursive 'tree of losers' ([PF_GetLoser\(\)](#)) and writes them to the outputfile.

Returns

1 if the sorting on the master was done. 0 if [EndSort\(\)](#) still must perform a regular sorting because it is not at the ground level or not on the master or in the sequential mode or in the InParallel mode. -1 if an error occurred.

Remarks

The slaves will send the sorted terms back to the master in the regular sorting (after the initialization of the send buffer in [PF_EndSort\(\)](#)). See [PutOut\(\)](#) and [FlushOut\(\)](#).

This function has been changed such that when it returns 1, AM.S0->TermsLeft is set correctly. But AM.S0->GenTerms is not set: it will be set after collecting the statistics from the slaves at the end of [PF_Processor\(\)](#). (TU 30 Jun 2011)

Definition at line 864 of file [parallel.c](#).

References [FlushOut\(\)](#), and [PutOut\(\)](#).

Referenced by [EndSort\(\)](#).

Here is the call graph for this function:

**4.95.4.12 PF_Deferred()**

```
WORD PF_Deferred (
    WORD * term,
    WORD level )
```

Replaces [Deferred\(\)](#) on the slaves.

Parameters

<i>term</i>	the term that must be multiplied by the contents of the current bracket.
<i>level</i>	the compiler level.

Returns

0 if OK, nonzero on error.

Definition at line 1208 of file [parallel.c](#).

References [Generator\(\)](#), and [InsertTerm\(\)](#).

Referenced by [Generator\(\)](#).

Here is the call graph for this function:

4.95.4.13 PF_Processor()

```
int PF_Processor (
    EXPRESSIONS e,
    WORD i,
    WORD LastExpression )
```

Replaces parts of [Processor\(\)](#) on the masters and slaves. On the master [PF_Processor\(\)](#) is responsible for proper distribution of terms from the input file to the slaves. On the slaves it calls [Generator\(\)](#) for all the terms that this process gets, but [PF_GetTerm\(\)](#) gets terms from the master (not directly from infile).

Parameters

<i>e</i>	The pointer to the current expression.
<i>i</i>	The index for the current expression.
<i>LastExpression</i>	The flag indicating whether it is the last expression.

Returns

0 if OK, nonzero on error.

Definition at line 1540 of file [parallel.c](#).

References [EndSort\(\)](#), [Generator\(\)](#), [LowerSortLevel\(\)](#), [NewSort\(\)](#), [PACK_LONG](#), [PF_BroadcastRedefinedPreVars\(\)](#), [PF_ISendSbuf\(\)](#), [PF_LongSinglePack\(\)](#), [PF_LongSingleReceive\(\)](#), [PF_LongSingleSend\(\)](#), [PF_LongSingleUnpack\(\)](#), [PF_PrepareLongSinglePack\(\)](#), [poly_factorize_expression\(\)](#), [poly_unfactorize_expression\(\)](#), [PutOut\(\)](#), [StoreTerm\(\)](#), [SWAP](#), [TimeCPU\(\)](#), and [WriteStats\(\)](#).

Here is the call graph for this function:

4.95.4.14 PF_Init()

```
int PF_Init (
    int * argc,
    char *** argv )
```

All the library independent stuff. [PF_LibInit\(\)](#) should do all library dependent initializations.

Parameters

<i>argc</i>	pointer to the number of arguments.
<i>argv</i>	pointer to the arguments.

Returns

0 if OK, nonzero on error.

Definition at line 1963 of file [parallel.c](#).

References [PF_Broadcast\(\)](#), [PF_LibInit\(\)](#), [PF_Pack\(\)](#), [PF_PreparePack\(\)](#), [PF_RealTime\(\)](#), and [PF_Unpack\(\)](#).

Here is the call graph for this function:

**4.95.4.15 PF_Terminate()**

```
int PF_Terminate (
    int errorcode )
```

Performs the finalization of ParFORM. To be called by `Terminate()`.

Parameters

<i>error</i>	an error code.
--------------	----------------

Returns

0 if OK, nonzero on error.

Definition at line 2058 of file [parallel.c](#).

References [PF_LibTerminate\(\)](#).

Here is the call graph for this function:

4.95.4.16 PF_GetSlaveTimes()

```
LONG PF_GetSlaveTimes (
    void )
```

Returns the total CPU time of all slaves together. This function must be called on the master and all slaves.

Returns

on the master, the sum of CPU times on all slaves.

Definition at line 2074 of file [parallel.c](#).

References [TimeCPU\(\)](#).

Here is the call graph for this function:

4.95.4.17 PF_BroadcastNumber()

```
LONG PF_BroadcastNumber (
    LONG x )
```

Broadcasts a LONG value from the master to the all slaves.

Parameters

x	the number to be broadcast (set on the master).
---	---

Returns

the synchronised result.

Definition at line 2094 of file [parallel.c](#).

References [PF_Bcast\(\)](#).

Referenced by [DoCheckpoint\(\)](#), [PF_BroadcastBuffer\(\)](#), and [StartVariables\(\)](#).

Here is the call graph for this function:

**4.95.4.18 PF_BroadcastBuffer()**

```
void PF_BroadcastBuffer (
    WORD ** buffer,
    LONG * length )
```

Broadcasts a buffer from the master to all the slaves.

Parameters

<i>in, out</i>	<i>buffer</i>	on the master, the buffer to be broadcast. On the slaves, the buffer will be allocated if the length is greater than 0. The caller must free it.
<i>in, out</i>	<i>length</i>	on the master, the length of the buffer to be broadcast. On the slaves, it receives the length of transferred buffer. The actual transfer occurs only if the length is greater than 0.

Definition at line 2121 of file [parallel.c](#).

References [PF_Bcast\(\)](#), and [PF_BroadcastNumber\(\)](#).

Here is the call graph for this function:

4.95.4.19 PF_BroadcastString()

```
int PF_BroadcastString (
    UBYTE * str )
```

Broadcasts a string from the master to all slaves.

Parameters

<i>in, out</i>	<i>str</i>	The pointer to a null-terminated string.
----------------	------------	--

Returns

0 if OK, nonzero on error.

Definition at line 2163 of file [parallel.c](#).

References [PF_Broadcast\(\)](#), [PF_PackString\(\)](#), [PF_PreparePack\(\)](#), and [PF_UnpackString\(\)](#).

Here is the call graph for this function:

**4.95.4.20 PF_BroadcastPreDollar()**

```
int PF_BroadcastPreDollar (
    WORD ** dbuffer,
    LONG * newsize,
    int * numterms )
```

Broadcasts dollar variables set as a preprocessor variables. Only the master is able to make an assignment like `#$a=g;` where `g` is an expression: only the master has an access to the expression. So, the master broadcasts the result to slaves.

The result is in `*dbuffer` of the size is `*newsize` (in number of WORDs), +1 for trailing zero. For slave `newsize` and `numterms` are output parameters.

Parameters

<i>in, out</i>	<i>dbuffer</i>	the buffer for a dollar variable.
<i>in, out</i>	<i>newsize</i>	the size of the dollar variable in WORDs.
<i>in, out</i>	<i>numterms</i>	the number of terms in the dollar variable.

Returns

0 if OK, nonzero on error.

Definition at line 2218 of file [parallel.c](#).

References [PF_Broadcast\(\)](#), [PF_Pack\(\)](#), [PF_PreparePack\(\)](#), and [PF_Unpack\(\)](#).

Here is the call graph for this function:

**4.95.4.21 PF_CollectModifiedDollars()**

```
int PF_CollectModifiedDollars (
    void )
```

Combines modified dollar variables on the all slaves, and store them into those on the master.

The potentially modified dollar variables are given in `PotModdollars`, and the number of them is given by `NumPotModdollars`.

The current module could be executed in parallel only if all potentially modified variables are listed in `ModOptdollars`, otherwise the module was switched to the sequential mode.

Returns

0 if OK, nonzero on error.

Definition at line 2505 of file parallel.c.

Here is the call graph for this function:

4.95.4.22 PF_BroadcastModifiedDollars()

```
int PF_BroadcastModifiedDollars (
    void )
```

Broadcasts modified dollar variables on the master to the all slaves.

The potentially modified dollar variables are given in PotModdollars, and the number of them is given by NumPotModdollars.

The current module could be executed in parallel only if all potentially modified variables are listed in `ModOptdollars`, otherwise the module was switched to the sequential mode. In either cases, we need to broadcast them.

Returns

0 if OK, nonzero on error.

Definition at line 2784 of file [parallel.c](#).

References [PF_LongMultiBroadcast\(\)](#), and [PF_PrepareLongMultiPack\(\)](#).

Here is the call graph for this function:

**4.95.4.23 PF_BroadcastRedefinedPreVars()**

```
int PF_BroadcastRedefinedPreVars (
    void )
```

Broadcasts preprocessor variables, which were changed by the Redefine statements in the current module, from the master to the all slaves.

The potentially redefined preprocessor variables are given in `AC.pfirstnum`, and the number of them is given by `AC.numpfirstnum`. For an actually redefined variable, the corresponding value in `AC.inputnumbers` is non-negative.

Returns

0 if OK, nonzero on error.

Definition at line 3001 of file [parallel.c](#).

References [PF_LongMultiBroadcast\(\)](#), [PF_PrepareLongMultiPack\(\)](#), [PutPreVar\(\)](#), [VectorPtr](#), and [VectorReserve](#).

4.95.4.24 PF_StoreInsideInfo()

```
int PF_StoreInsideInfo (
    void )
```

Definition at line 3091 of file [parallel.c](#).

4.95.4.25 PF_RestoreInsideInfo()

```
int PF_RestoreInsideInfo (
    void )
```

Definition at line 3117 of file [parallel.c](#).

4.95.4.26 PF_BroadcastCBuf()

```
int PF_BroadcastCBuf (
    int bufnum )
```

Broadcasts a compiler buffer specified by *bufnum* from the master to the all slaves.

Parameters

<i>bufnum</i>	The index of the compiler buffer to be broadcast.
---------------	---

Returns

0 if OK, nonzero on error.

Definition at line 3143 of file [parallel.c](#).

References [CbUf::boomlijst](#), [CbUf::Buffer](#), [CbUf::BufferSize](#), [CbUf::CanCommu](#), [CbUf::dimension](#), [finishcbuf\(\)](#), [CbUf::lhs](#), [CbUf::numdum](#), [CbUf::NumTerms](#), [PF_LongMultiBroadcast\(\)](#), [PF_PrepareLongMultiPack\(\)](#), [CbUf::Pointer](#), [CbUf::rhs](#), and [CbUf::Top](#).

Here is the call graph for this function:

4.95.4.27 PF_BroadcastExpFlags()

```
int PF_BroadcastExpFlags (
    void )
```

Broadcasts AR.expflags and several properties of each expression, e.g., e->vflags, from the master to all slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3254 of file [parallel.c](#).

References [PF_LongMultiBroadcast\(\)](#), and [PF_PrepareLongMultiPack\(\)](#).

Here is the call graph for this function:

4.95.4.28 PF_BroadcastExpr()

```
int PF_BroadcastExpr (
    EXPRESSIONS e,
    FILEHANDLE * file )
```

Broadcasts an expression from the master to the all slaves.

Parameters

<i>e</i>	The expression to be broadcast.
<i>file</i>	The file in which the expression is sitting.

Returns

0 if OK, nonzero on error.

Definition at line 3548 of file [parallel.c](#).

Referenced by [PF_BroadcastRHS\(\)](#).

4.95.4.29 PF_BroadcastRHS()

```
int PF_BroadcastRHS (
    void )
```

Broadcasts expressions appearing in the right-hand side from the master to the all slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3576 of file [parallel.c](#).

References [PF_BroadcastExpr\(\)](#).

Referenced by [Processor\(\)](#).

Here is the call graph for this function:

4.95.4.30 PF_InParallelProcessor()

```
int PF_InParallelProcessor (
    void )
```

Processes expressions in the InParallel mode, i.e., dividing expressions marked by partodo over the slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3623 of file [parallel.c](#).

Referenced by [Processor\(\)](#).

4.95.4.31 PF_SendFile()

```
int PF_SendFile (
    int to,
    FILE * fd )
```

Sends a file to the process specified by *to*.

Parameters

<i>to</i>	the destination process number.
<i>fd</i>	the file to be sent.

Returns

the size of sent data in bytes, or -1 on error.

Definition at line 4220 of file [parallel.c](#).

References [PF_RawSend\(\)](#).

Referenced by [DoCheckpoint\(\)](#).

Here is the call graph for this function:

**4.95.4.32 PF_RecvFile()**

```
int PF_RecvFile (
    int from,
    FILE * fd )
```

Receives a file from the process specified by *from*.

Parameters

<i>from</i>	the source process number.
<i>fd</i>	the file to save the received data.

Returns

the size of received data in bytes, or -1 on error.

Definition at line 4258 of file [parallel.c](#).

References [PF_RawRecv\(\)](#).

Referenced by [DoCheckpoint\(\)](#).

Here is the call graph for this function:

4.95.4.33 PF_MLock()

```
void PF_MLock (
    void )
```

A function called by MLOCK(ErrorMessageLock) for slaves.

Definition at line 4339 of file [parallel.c](#).

References [VectorClear](#).

4.95.4.34 PF_MUnlock()

```
void PF_MUnlock (
    void )
```

A function called by MUNLOCK(ErrorMessageLock) for slaves.

Definition at line 4355 of file [parallel.c](#).

References [PF_RawSend\(\)](#), [VectorEmpty](#), [VectorPtr](#), and [VectorSize](#).

Here is the call graph for this function:

4.95.4.35 PF_WriteFileToFile()

```
LONG PF_WriteFileToFile (
    int handle,
    UBYTE * buffer,
    LONG size )
```

Replaces WriteFileToFile() on the master and slaves.

It copies the given buffer into internal buffers if called between MLOCK(ErrorMessageLock) and MUNLOCK(ErrorMessageLock) for slaves and handle is StdOut or LogHandle, otherwise calls WriteFileToFile().

Parameters

<i>handle</i>	a file handle that specifies the output.
<i>buffer</i>	a pointer to the source buffer containing the data to be written.
<i>size</i>	the size of data to be written in bytes.

Returns

the actual size of data written to the output in bytes.

Definition at line 4384 of file [parallel.c](#).

References [VectorClear](#), [VectorPtr](#), [VectorPushBacks](#), and [VectorSize](#).

4.95.4.36 PF_FlushStdOutBuffer()

```
void PF_FlushStdOutBuffer (
    void )
```

Explicitly Flushes the buffer for the standard output on the master, which is used if PF_ENABLE_STDOUT_↵
BUFFERING is defined.

Definition at line 4478 of file [parallel.c](#).

References [VectorClear](#), [VectorPtr](#), and [VectorSize](#).

4.95.4.37 PF_FreeErrorMessageBuffers()

```
void PF_FreeErrorMessageBuffers (
    void )
```

Frees the buffers allocated for the synchronized output.

Currently, not used anywhere, but could be used in [PF_Terminate\(\)](#).

Definition at line 4614 of file [parallel.c](#).

References [VectorFree](#).

```

```

04284 /*
04285  * If the master and slaves output statistics or error messages to the same stream
04286  * or file (e.g., the standard output or the log file) simultaneously, then
04287  * a mixing of their outputs can occur. To avoid this, TFORM uses a lock of
04288  * ErrorMessageLock, but there is no locking functionality in the original MPI
04289  * specification. We need to synchronise the output from the master and slaves.
04290  *
04291  * The idea of the synchronised output (by, e.g., MesPrint()) implemented here is
04292  * Slaves:
04293  * 1. Save the output by WriteFile() (set to PF_WriteFileToFile())
04294  *    into some buffers between MLOCK(ErrorMessageLock) and
04295  *    MUNLOCK(ErrorMessageLock), which call PF_MLock() and PF_MUnlock(),
04296  *    respectively. The output for AM.StdOut and AC.LogHandle are saved to
04297  *    the buffers.
04298  * 2. At MUNLOCK(ErrorMessageLock), send the output in the buffer to the master,
04299  *    with PF_STDOUT_MSGTAG or PF_LOG_MSGTAG.
04300  * Master:
04301  * 1. Receive the buffered output from slaves, and write them by
04302  *    WriteFileToFile().
04303  * The main problem is how and where the master receives messages from
04304  * the slaves (PF_ReceiveErrorMessage()). For this purpose there are three
04305  * helper functions: PF_CatchErrorMessages() and PF_CatchErrorMessagesForAll()
04306  * which remove messages with PF_STDOUT_MSGTAG or PF_LOG_MSGTAG from the top
04307  * of the message queue, and PF_ProbeWithCatchingErrorMessages() which is same as
04308  * PF_Probe() except removing these messages.

04397 /*
04398  * On my computer, sometimes a single linefeed "\n" sent to the standard
04399  * output is ignored on the execution of mpiexec. A typical example is:
04400  * $ cat foo.c
04401  * #include <unistd.h>
04402  * int main() {
04403  *     write(1, "      ", 4);
04404  *     write(1, "\n", 1);
04405  *     write(1, "      ", 4);
04406  *     write(1, "123\n", 4);
04407  *     return 0;
04408  * }
04409  * or even as a shell script:
04410  * $ cat foo.sh
04411  * #! bin/sh
04412  * printf "      "
04413  * printf "\n"
04414  * printf "      "
04415  * printf "123\n"
04416  * When I ran it on mpiexec
04417  * $ while :; do mpiexec -np 1 ./foo.sh; done
04418  * I observed the single linefeed (printf "\n") was sometimes ignored. Even
04419  * though this phenomenon might be specific to my environment, I added this
04420  * code because someone may encounter a similar phenomenon and feel it
04421  * frustrating. (TU 16 Jun 2011)
04422  *
04423  * Phenomenon:
04424  * A single linefeed sent to the standard output occasionally ignored
04425  * on mpiexec.
04426  *
04427  * Environment:
04428  * openSUSE 11.4 (x86_64)
04429  * kernel: 2.6.37.6-0.5-desktop
04430  * gcc: 4.5.1 20101208
04431  * mpich2-1.3.2p1 configured with '--enable-shared --with-pm=smpd'
04432  *
04433  * Solution:
04434  * In Unix (in which Uwrite() calls write() system call without any buffering),
04435  * we perform the line buffering here. A single linefeed is also buffered.
04436  *
04437  * XXX:
04438  * At the end of the program the buffered output (text without LF) will not be flushed,
04439  * i.e., will not be written to the standard output. This is not problematic at a normal run.
04440  * The buffer can be explicitly flushed by PF_FlushStdOutBuffer().

4.97.3 Function Documentation

4.97.3.1 PF_IsendSbuf()

```
int PF_IsendSbuf (  
    int to,  
    int tag ) [extern]
```

Nonblocking send operation. It sends everything from *buff* to *fill* of the active buffer. Depending on *tag* it also can do waiting for other sends to finish or set the active buffer to the next one.

Parameters

<i>to</i>	the destination process number.
<i>tag</i>	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 261 of file [mpi.c](#).

Referenced by [FlushOut\(\)](#), [PF_Processor\(\)](#), and [PutOut\(\)](#).

4.97.3.2 PF_Bcast()

```
int PF_Bcast (
    void * buffer,
    int count ) [extern]
```

Broadcasts a message from the master to slaves.

Parameters

<i>in, out</i>	<i>buffer</i>	the starting address of buffer. The contents in this buffer on the master will be transferred to those on the slaves.
	<i>count</i>	the length of the buffer in bytes.

Returns

0 if OK, nonzero on error.

Definition at line [440](#) of file [mpi.c](#).

Referenced by [PF_BroadcastBuffer\(\)](#), and [PF_BroadcastNumber\(\)](#).

4.97.3.3 PF_RawSend()

```
int PF_RawSend (
    int dest,
    void * buf,
    LONG l,
    int tag ) [extern]
```

Sends *l* bytes from *buf* to *dest*. Returns 0 on success, or -1.

Parameters

<i>dest</i>	the destination process number.
<i>buf</i>	the send buffer.
<i>l</i>	the size of data in the send buffer in bytes.
<i>tag</i>	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line [463](#) of file [mpi.c](#).

4.97.3.4 PF_RawRecv()

```
LONG PF_RawRecv (
    int * src,
```

```
void * buf,
LONG thesize,
int * tag ) [extern]
```

Receives not more than *thesize* bytes from *src*, returns the actual number of received bytes, or -1 on failure.

Parameters

in, out	<i>src</i>	the source process number. In output, that of the actual received message.
out	<i>buf</i>	the receive buffer.
	<i>thesize</i>	the size of the receive buffer in bytes.
out	<i>tag</i>	the message tag of the actual received message.

Returns

the actual sizeof received data in bytes, or -1 on failure.

Definition at line 484 of file [mpi.c](#).

4.97.3.5 PF_PreparePack()

```
int PF_PreparePack (
    void ) [extern]
```

Prepares for the next pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 624 of file [mpi.c](#).

Referenced by [Optimize\(\)](#), [PF_BroadcastPreDollar\(\)](#), [PF_BroadcastString\(\)](#), and [PF_Init\(\)](#).

4.97.3.6 PF_Pack()

```
int PF_Pack (
    const void * buffer,
    size_t count,
    MPI_Datatype type ) [extern]
```

Adds data into the pack buffer.

Parameters

<i>buffer</i>	the pointer to the buffer storing the data to be packed.
<i>count</i>	the number of elements in the buffer.
<i>type</i>	the data type of elements in the buffer.

Returns

0 if OK, nonzero on error.

Definition at line 642 of file [mpi.c](#).

References [MPI_ERRCODE_CHECK](#).

Referenced by [Optimize\(\)](#), [PF_BroadcastPreDollar\(\)](#), and [PF_Init\(\)](#).

4.97.3.7 PF_Unpack()

```
int PF_Unpack (
    void * buffer,
    size_t count,
    MPI_Datatype type ) [extern]
```

Retrieves the next data in the pack buffer.

Parameters

out	<i>buffer</i>	the pointer to the buffer to store the unpacked data.
	<i>count</i>	the number of elements of data to be received.
	<i>type</i>	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 671 of file [mpi.c](#).

References [MPI_ERRCODE_CHECK](#).

Referenced by [Optimize\(\)](#), [PF_BroadcastPreDollar\(\)](#), and [PF_Init\(\)](#).

4.97.3.8 PF_PackString()

```
int PF_PackString (
    const UBYTE * str ) [extern]
```

Packs a string *str* into the packed buffer `PF_packbuf`, including the trailing zero.

The first element (`PF_INT`) is the length of the packed portion of the string. If the string does not fit to the buffer `PF_packbuf`, the function packs only the initial portion. It returns the number of packed bytes, so if `(str[length-1]=='\0')` then the whole string fits to the buffer, if not, then the rest (`str+length`) must be packed and send again. On error, the function returns the negative error code.

One exception: the string `"\0\0"` is used as an image of the NULL, so all 3 characters will be packed.

Parameters

<i>str</i>	a string to be packed.
------------	------------------------

Returns

the number of packed bytes, or a negative value on failure.

Definition at line 706 of file [mpi.c](#).

Referenced by [PF_BroadcastString\(\)](#).

4.97.3.9 PF_UnpackString()

```
int PF_UnpackString (
    UBYTE * str ) [extern]
```

Unpacks a string to *str* from the packed buffer PF_packbuf, including the trailing zero.

It returns the number of unpacked bytes, so if (str[length-1]=='\0') then the whole string was unpacked, if not, then the rest must be appended to (str+length). On error, the function returns the negative error code.

Parameters

out	<i>str</i>	the buffer to store the unpacked string
-----	------------	---

Returns

the number of unpacked bytes, or a negative value on failure.

Definition at line 774 of file [mpi.c](#).

Referenced by [PF_BroadcastString\(\)](#).

4.97.3.10 PF_Send()

```
int PF_Send (
    int to,
    int tag ) [extern]
```

Sends the contents in the pack buffer to the process specified by *to*.

Example:

```
if ( PF.me == SRC ) {
    PF_PreparePack();
    // Packing operations here...
    PF_Send(DEST, TAG);
}
else if ( PF.me == DEST ) {
    PF_Receive(SRC, TAG, &actual_src, &actual_tag);
    // Unpacking operations here...
}
```

Parameters

<i>to</i>	the destination process number.
<i>tag</i>	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 822 of file [mpi.c](#).

References [MPI_ERRCODE_CHECK](#).

4.97.3.11 PF_Receive()

```
int PF_Receive (
    int src,
    int tag,
    int * psrc,
    int * ptag ) [extern]
```

Receives data into the pack buffer from the process specified by *src*. This function allows &*src* == *psrc* or &*tag* == *ptag*. Either *psrc* or *ptag* can be NULL.

See the example of [PF_Send\(\)](#).

Parameters

	<i>src</i>	the source process number (can be PF_ANY_SOURCE).
	<i>tag</i>	the source message tag (can be PF_ANY_TAG).
out	<i>psrc</i>	the actual source process number of received message.
out	<i>ptag</i>	the received message tag.

Returns

0 if OK, nonzero on error.

Definition at line 848 of file [mpi.c](#).

References [MPI_ERRCODE_CHECK](#).

4.97.3.12 PF_Broadcast()

```
int PF_Broadcast (
    void ) [extern]
```

Broadcasts the contents in the pack buffer on the master to those on the slaves.

Example:

```
if ( PF.me == MASTER ) {
    PF_PreparePack();
    // Packing operations here...
}
PF_Broadcast();
if ( PF.me != MASTER ) {
    // Unpacking operations here...
}
```

Returns

0 if OK, nonzero on error.

Definition at line 883 of file [mpi.c](#).

References [MPI_ERRCODE_CHECK](#).

Referenced by [Optimize\(\)](#), [PF_BroadcastPreDollar\(\)](#), [PF_BroadcastString\(\)](#), and [PF_Init\(\)](#).

4.97.3.13 PF_PrepareLongSinglePack()

```
int PF_PrepareLongSinglePack (
    void ) [extern]
```

Prepares for the next long-single-pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 1451 of file [mpi.c](#).

Referenced by [PF_CollectModifiedDollars\(\)](#), and [PF_Processor\(\)](#).

4.97.3.14 PF_LongSinglePack()

```
int PF_LongSinglePack (
    const void * buffer,
    size_t count,
    MPI_Datatype type ) [extern]
```

Adds data into the "long single" pack buffer.

Parameters

<i>buffer</i>	the pointer to the buffer storing the data to be packed.
<i>count</i>	the number of elements in the buffer.
<i>type</i>	the data type of elements in the buffer.

Returns

0 if OK, nonzero on error.

Definition at line 1469 of file [mpi.c](#).

Referenced by [PF_CollectModifiedDollars\(\)](#), and [PF_Processor\(\)](#).

4.97.3.15 PF_LongSingleUnpack()

```
int PF_LongSingleUnpack (
    void * buffer,
    size_t count,
    MPI_Datatype type ) [extern]
```

Retrieves the next data in the "long single" pack buffer.

Parameters

out	<i>buffer</i>	the pointer to the buffer to store the unpacked data.
	<i>count</i>	the number of elements of data to be received.
	<i>type</i>	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 1503 of file [mpi.c](#).

Referenced by [PF_CollectModifiedDollars\(\)](#), and [PF_Processor\(\)](#).

4.97.3.16 PF_LongSingleSend()

```
int PF_LongSingleSend (
    int to,
    int tag ) [extern]
```

Sends the contents in the "long single" pack buffer to the process specified by *to*.

Example:

```
if ( PF.me == SRC ) {
    PF_PrepareLongSinglePack();
    // Packing operations here...
    PF_LongSingleSend(DEST, TAG);
}
else if ( PF.me == DEST ) {
    PF_LongSingleReceive(SRC, TAG, &actual_src, &actual_tag);
    // Unpacking operations here...
}
```

Parameters

<i>to</i>	the destination process number.
<i>tag</i>	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 1540 of file [mpi.c](#).

Referenced by [PF_CollectModifiedDollars\(\)](#), and [PF_Processor\(\)](#).

4.97.3.17 PF_LongSingleReceive()

```
int PF_LongSingleReceive (
    int src,
    int tag,
    int * psrc,
    int * ptag ) [extern]
```

Receives data into the "long single" pack buffer from the process specified by *src*. This function allows *&src == psrc* or *&tag == ptag*. Either *psrc* or *ptag* can be NULL.

See the example of [PF_LongSingleSend\(\)](#).

Parameters

	<i>src</i>	the source process number (can be PF_ANY_SOURCE).
	<i>tag</i>	the source message tag (can be PF_ANY_TAG).
out	<i>psrc</i>	the actual source process number of received message.
out	<i>ptag</i>	the received message tag.

Returns

0 if OK, nonzero on error.

Definition at line 1583 of file [mpi.c](#).

Referenced by [PF_CollectModifiedDollars\(\)](#), and [PF_Processor\(\)](#).

4.97.3.18 PF_PrepareLongMultiPack()

```
int PF_PrepareLongMultiPack (
    void ) [extern]
```

Prepares for the next long-multi-pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 1643 of file [mpi.c](#).

Referenced by [Optimize\(\)](#), [PF_BroadcastCBuf\(\)](#), [PF_BroadcastExpFlags\(\)](#), [PF_BroadcastModifiedDollars\(\)](#), and [PF_BroadcastRedefinedPreVars\(\)](#).

4.97.3.19 PF_LongMultiPackImpl()

```
int PF_LongMultiPackImpl (
    const void * buffer,
    size_t count,
    size_t eSize,
    MPI_Datatype type ) [extern]
```

Adds data into the "long multi" pack buffer.

Parameters

<i>buffer</i>	the pointer to the buffer storing the data to be packed.
<i>count</i>	the number of elements in the buffer.
<i>eSize</i>	the byte size of each element of data.
<i>type</i>	the data type of elements in the buffer.

Returns

0 if OK, nonzero on error.

Definition at line 1662 of file [mpi.c](#).

References [PF_LongMultiPackImpl\(\)](#).

Referenced by [PF_LongMultiPackImpl\(\)](#).

Here is the call graph for this function:

**4.97.3.20 PF_LongMultiUnpackImpl()**

```

int PF_LongMultiUnpackImpl (
    void * buffer,
    size_t count,
    size_t eSize,
    MPI_Datatype type ) [extern]
  
```

Retrieves the next data in the "long multi" pack buffer.

Parameters

out	<i>buffer</i>	the pointer to the buffer to store the unpacked data.
	<i>count</i>	the number of elements of data to be received.
	<i>eSize</i>	the byte size of each element of data.
	<i>type</i>	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 1721 of file [mpi.c](#).

References [PF_LongMultiUnpackImpl\(\)](#).

Referenced by [PF_LongMultiUnpackImpl\(\)](#).

Here is the call graph for this function:

4.97.3.21 PF_LongMultiBroadcast()

```
int PF_LongMultiBroadcast (
    void ) [extern]
```

Broadcasts the contents in the "long multi" pack buffer on the master to those on the slaves.

Example:

```
if ( PF.me == MASTER ) {
    PF_PrepareLongMultiPack();
    // Packing operations here...
}
PF_LongMultiBroadcast();
if ( PF.me != MASTER ) {
    // Unpacking operations here...
}
```

Returns

0 if OK, nonzero on error.

Definition at line 1807 of file [mpi.c](#).

Referenced by [Optimize\(\)](#), [PF_BroadcastCBuf\(\)](#), [PF_BroadcastExpFlags\(\)](#), [PF_BroadcastModifiedDollars\(\)](#), and [PF_BroadcastRedefinedPreVars\(\)](#).

4.97.3.22 PF_EndSort()

```
int PF_EndSort (
    void ) [extern]
```

Finishes a master sorting with collecting terms from slaves. Called by [EndSort\(\)](#).

If this is not the masterprocess, just initialize the sendbuffers and return 0, else [PF_EndSort\(\)](#) sends the rest of the terms in the sendbuffer to the next slave and a dummy message to all slaves with tag PF_ENDSORT_MSGTAG. Then it receives the sorted terms, sorts them using a recursive 'tree of losers' ([PF_GetLoser\(\)](#)) and writes them to the outputfile.

Returns

1 if the sorting on the master was done. 0 if [EndSort\(\)](#) still must perform a regular sorting because it is not at the ground level or not on the master or in the sequential mode or in the InParallel mode. -1 if an error occurred.

Remarks

The slaves will send the sorted terms back to the master in the regular sorting (after the initialization of the send buffer in [PF_EndSort\(\)](#)). See [PutOut\(\)](#) and [FlushOut\(\)](#).

This function has been changed such that when it returns 1, AM.S0->TermsLeft is set correctly. But AM.S0->GenTerms is not set: it will be set after collecting the statistics from the slaves at the end of [PF_Processor\(\)](#). (TU 30 Jun 2011)

Definition at line 864 of file [parallel.c](#).

References [FlushOut\(\)](#), and [PutOut\(\)](#).

Referenced by [EndSort\(\)](#).

Here is the call graph for this function:

**4.97.3.23 PF_Deferred()**

```
WORD PF_Deferred (
    WORD * term,
    WORD level ) [extern]
```

Replaces [Deferred\(\)](#) on the slaves.

Parameters

<i>term</i>	the term that must be multiplied by the contents of the current bracket.
<i>level</i>	the compiler level.

Returns

0 if OK, nonzero on error.

Definition at line 1208 of file [parallel.c](#).

References [Generator\(\)](#), and [InsertTerm\(\)](#).

Referenced by [Generator\(\)](#).

Here is the call graph for this function:

4.97.3.24 PF_Processor()

```
int PF_Processor (
    EXPRESSIONS e,
    WORD i,
    WORD LastExpression ) [extern]
```

Replaces parts of [Processor\(\)](#) on the masters and slaves. On the master [PF_Processor\(\)](#) is responsible for proper distribution of terms from the input file to the slaves. On the slaves it calls [Generator\(\)](#) for all the terms that this process gets, but [PF_GetTerm\(\)](#) gets terms from the master (not directly from infile).

Parameters

<i>e</i>	The pointer to the current expression.
<i>i</i>	The index for the current expression.
<i>LastExpression</i>	The flag indicating whether it is the last expression.

Returns

0 if OK, nonzero on error.

Definition at line 1540 of file [parallel.c](#).

References [EndSort\(\)](#), [Generator\(\)](#), [LowerSortLevel\(\)](#), [NewSort\(\)](#), [PACK_LONG](#), [PF_BroadcastRedefinePreVars\(\)](#), [PF_ISendSbuf\(\)](#), [PF_LongSinglePack\(\)](#), [PF_LongSingleReceive\(\)](#), [PF_LongSingleSend\(\)](#), [PF_LongSingleUnpack\(\)](#), [PF_PrepareLongSinglePack\(\)](#), [poly_factorize_expression\(\)](#), [poly_unfactorize_expression\(\)](#), [PutOut\(\)](#), [StoreTerm\(\)](#), [SWAP](#), [TimeCPU\(\)](#), and [WriteStats\(\)](#).

Here is the call graph for this function:

4.97.3.25 PF_Init()

```
int PF_Init (
    int * argc,
    char *** argv ) [extern]
```

All the library independent stuff. [PF_LibInit\(\)](#) should do all library dependent initializations.

Parameters

<i>argc</i>	pointer to the number of arguments.
<i>argv</i>	pointer to the arguments.

Returns

0 if OK, nonzero on error.

Definition at line 1963 of file [parallel.c](#).

References [PF_Broadcast\(\)](#), [PF_LibInit\(\)](#), [PF_Pack\(\)](#), [PF_PreparePack\(\)](#), [PF_RealTime\(\)](#), and [PF_Unpack\(\)](#).

Here is the call graph for this function:

4.97.3.26 PF_Terminate()

```
int PF_Terminate (
    int errorcode ) [extern]
```

Performs the finalization of ParFORM. To be called by `Terminate()`.

Parameters

<i>error</i>	an error code.
--------------	----------------

Returns

0 if OK, nonzero on error.

Definition at line 2058 of file [parallel.c](#).

References [PF_LibTerminate\(\)](#).

Here is the call graph for this function:

4.97.3.27 PF_GetSlaveTimes()

```
LONG PF_GetSlaveTimes (
    void ) [extern]
```

Returns the total CPU time of all slaves together. This function must be called on the master and all slaves.

Returns

on the master, the sum of CPU times on all slaves.

Definition at line 2074 of file [parallel.c](#).

References [TimeCPU\(\)](#).

Here is the call graph for this function:

4.97.3.28 PF_BroadcastNumber()

```
LONG PF_BroadcastNumber (
    LONG x ) [extern]
```

Broadcasts a LONG value from the master to the all slaves.

Parameters

x	the number to be broadcast (set on the master).
---	---

Returns

the synchronised result.

Definition at line 2094 of file [parallel.c](#).

References [PF_Bcast\(\)](#).

Referenced by [DoCheckpoint\(\)](#), [PF_BroadcastBuffer\(\)](#), and [StartVariables\(\)](#).

Here is the call graph for this function:

**4.97.3.29 PF_BroadcastBuffer()**

```

void PF_BroadcastBuffer (
    WORD ** buffer,
    LONG * length ) [extern]
  
```

Broadcasts a buffer from the master to all the slaves.

Parameters

in, out	<i>buffer</i>	on the master, the buffer to be broadcast. On the slaves, the buffer will be allocated if the length is greater than 0. The caller must free it.
in, out	<i>length</i>	on the master, the length of the buffer to be broadcast. On the slaves, it receives the length of transferred buffer. The actual transfer occurs only if the length is greater than 0.

Definition at line 2121 of file [parallel.c](#).

References [PF_Bcast\(\)](#), and [PF_BroadcastNumber\(\)](#).

Here is the call graph for this function:

4.97.3.30 PF_BroadcastString()

```
int PF_BroadcastString (
    UBYTE * str ) [extern]
```

Broadcasts a string from the master to all slaves.

Parameters

<i>in, out</i>	<i>str</i>	The pointer to a null-terminated string.
----------------	------------	--

Returns

0 if OK, nonzero on error.

Definition at line 2163 of file [parallel.c](#).

References [PF_Broadcast\(\)](#), [PF_PackString\(\)](#), [PF_PreparePack\(\)](#), and [PF_UnpackString\(\)](#).

Here is the call graph for this function:

4.97.3.31 PF_BroadcastPreDollar()

```
int PF_BroadcastPreDollar (
    WORD ** dbuffer,
    LONG * newsize,
    int * numterms ) [extern]
```

Broadcasts dollar variables set as a preprocessor variables. Only the master is able to make an assignment like `#$a=g;` where `g` is an expression: only the master has an access to the expression. So, the master broadcasts the result to slaves.

The result is in `*dbuffer` of the size is `*newsize` (in number of WORDs), +1 for trailing zero. For slave `newsize` and `numterms` are output parameters.

Parameters

<i>in, out</i>	<i>dbuffer</i>	the buffer for a dollar variable.
<i>in, out</i>	<i>newsize</i>	the size of the dollar variable in WORDs.
<i>in, out</i>	<i>numterms</i>	the number of terms in the dollar variable.

Returns

0 if OK, nonzero on error.

Definition at line 2218 of file [parallel.c](#).

References [PF_Broadcast\(\)](#), [PF_Pack\(\)](#), [PF_PreparePack\(\)](#), and [PF_Unpack\(\)](#).

Here is the call graph for this function:

4.97.3.32 PF_CollectModifiedDollars()

```
int PF_CollectModifiedDollars (
    void ) [extern]
```

Combines modified dollar variables on the all slaves, and store them into those on the master.

The potentially modified dollar variables are given in `PotModdollars`, and the number of them is given by `NumPotModdollars`.

The current module could be executed in parallel only if all potentially modified variables are listed in `ModOptdollars`, otherwise the module was switched to the sequential mode.

Returns

0 if OK, nonzero on error.

Definition at line 2784 of file [parallel.c](#).

References [PF_LongMultiBroadcast\(\)](#), and [PF_PrepareLongMultiPack\(\)](#).

Here is the call graph for this function:

**4.97.3.34 PF_BroadcastRedefinedPreVars()**

```
int PF_BroadcastRedefinedPreVars (  
    void ) [extern]
```

Broadcasts preprocessor variables, which were changed by the Redefine statements in the current module, from the master to the all slaves.

The potentially redefined preprocessor variables are given in `AC.pfirstnum`, and the number of them is given by `AC.numpfirstnum`. For an actually redefined variable, the corresponding value in `AC.inputnumbers` is non-negative.

Returns

0 if OK, nonzero on error.

Definition at line 3001 of file [parallel.c](#).

References [PF_LongMultiBroadcast\(\)](#), [PF_PrepareLongMultiPack\(\)](#), [PutPreVar\(\)](#), [VectorPtr](#), and [VectorReserve](#).

Here is the call graph for this function:

4.97.3.35 PF_BroadcastCBuf()

```
int PF_BroadcastCBuf (
    int bufnum ) [extern]
```

Broadcasts a compiler buffer specified by *bufnum* from the master to the all slaves.

Parameters

<i>bufnum</i>	The index of the compiler buffer to be broadcast.
---------------	---

Returns

0 if OK, nonzero on error.

Definition at line 3143 of file [parallel.c](#).

References [CbUf::boomlijst](#), [CbUf::Buffer](#), [CbUf::BufferSize](#), [CbUf::CanCommu](#), [CbUf::dimension](#), [finishcbuf\(\)](#), [CbUf::lhs](#), [CbUf::numdum](#), [CbUf::NumTerms](#), [PF_LongMultiBroadcast\(\)](#), [PF_PrepareLongMultiPack\(\)](#), [CbUf::Pointer](#), [CbUf::rhs](#), and [CbUf::Top](#).

Here is the call graph for this function:

4.97.3.36 PF_BroadcastExpFlags()

```
int PF_BroadcastExpFlags (
    void ) [extern]
```

Broadcasts `AR.expflags` and several properties of each expression, e.g., `e->vflags`, from the master to all slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3254 of file [parallel.c](#).

References [PF_LongMultiBroadcast\(\)](#), and [PF_PrepareLongMultiPack\(\)](#).

Here is the call graph for this function:

**4.97.3.37 PF_StoreInsideInfo()**

```
int PF_StoreInsideInfo (
    void ) [extern]
```

Definition at line 3091 of file [parallel.c](#).

4.97.3.38 PF_RestoreInsideInfo()

```
int PF_RestoreInsideInfo (
    void ) [extern]
```

Definition at line 3117 of file [parallel.c](#).

4.97.3.39 PF_BroadcastExpr()

```
int PF_BroadcastExpr (
    EXPRESSIONS e,
    FILEHANDLE * file ) [extern]
```

Broadcasts an expression from the master to the all slaves.

Parameters

<i>e</i>	The expression to be broadcast.
<i>file</i>	The file in which the expression is sitting.

Returns

0 if OK, nonzero on error.

Definition at line [3548](#) of file [parallel.c](#).

Referenced by [PF_BroadcastRHS\(\)](#).

4.97.3.40 PF_BroadcastRHS()

```
int PF_BroadcastRHS (
    void ) [extern]
```

Broadcasts expressions appearing in the right-hand side from the master to the all slaves.

Returns

0 if OK, nonzero on error.

Definition at line [3576](#) of file [parallel.c](#).

References [PF_BroadcastExpr\(\)](#).

Referenced by [Processor\(\)](#).

Here is the call graph for this function:

**4.97.3.41 PF_InParallelProcessor()**

```
int PF_InParallelProcessor (
    void ) [extern]
```

Processes expressions in the InParallel mode, i.e., dividing expressions marked by `partodo` over the slaves.

Returns

0 if OK, nonzero on error.

Definition at line [3623](#) of file [parallel.c](#).

Referenced by [Processor\(\)](#).

4.97.3.42 PF_SendFile()

```
int PF_SendFile (
    int to,
    FILE * fd ) [extern]
```

Sends a file to the process specified by `to`.

Parameters

<i>to</i>	the destination process number.
<i>fd</i>	the file to be sent.

Returns

the size of sent data in bytes, or -1 on error.

Definition at line 4220 of file [parallel.c](#).

References [PF_RawSend\(\)](#).

Referenced by [DoCheckpoint\(\)](#).

Here is the call graph for this function:

4.97.3.43 PF_RecvFile()

```
int PF_RecvFile (
    int from,
    FILE * fd ) [extern]
```

Receives a file from the process specified by *from*.

Parameters

<i>from</i>	the source process number.
<i>fd</i>	the file to save the received data.

Returns

the size of received data in bytes, or -1 on error.

Definition at line 4258 of file [parallel.c](#).

References [PF_RawRecv\(\)](#).

Referenced by [DoCheckpoint\(\)](#).

Here is the call graph for this function:

4.97.3.44 PF_MLock()

```
void PF_MLock (
    void ) [extern]
```

A function called by MLOCK(ErrorMessageLock) for slaves.

Definition at line 4339 of file [parallel.c](#).

References [VectorClear](#).

4.97.3.45 PF_MUnlock()

```
void PF_MUnlock (
    void ) [extern]
```

A function called by MUNLOCK(ErrorMessageLock) for slaves.

Definition at line 4355 of file [parallel.c](#).

References [PF_RawSend\(\)](#), [VectorEmpty](#), [VectorPtr](#), and [VectorSize](#).

Here is the call graph for this function:

4.97.3.46 PF_WriteFileToFile()

```
LONG PF_WriteFileToFile (
    int handle,
    UBYTE * buffer,
    LONG size ) [extern]
```

Replaces WriteFileToFile() on the master and slaves.

It copies the given buffer into internal buffers if called between MLOCK(ErrorMessageLock) and MUNLOCK(ErrorMessageLock) for slaves and handle is StdOut or LogHandle, otherwise calls WriteFileToFile().

Parameters

<i>handle</i>	a file handle that specifies the output.
<i>buffer</i>	a pointer to the source buffer containing the data to be written.
<i>size</i>	the size of data to be written in bytes.

Returns

the actual size of data written to the output in bytes.

Definition at line 4384 of file [parallel.c](#).

References [VectorClear](#), [VectorPtr](#), [VectorPushBacks](#), and [VectorSize](#).

4.97.3.47 PF_FlushStdOutBuffer()

```
void PF_FlushStdOutBuffer (
    void ) [extern]
```

Explicitly Flushes the buffer for the standard output on the master, which is used if PF_ENABLE_STDOUT_↵
BUFFERING is defined.

Definition at line 4478 of file [parallel.c](#).

References [VectorClear](#), [VectorPtr](#), and [VectorSize](#).

4.99.1 Detailed Description

Top level pattern matching routines. More pattern matching is found in [findpat.c](#), [function.c](#), [symmetr.c](#) and [smart.c](#). The last three files contain the matching inside functions. The file [pattern.c](#) contains also the very important routine `Substitute`. All regular pattern matching is just the finding of the pattern and indicating what are the wildcards etc. The routine `Substitute` does the actual removal of the pattern and replaces it by a subterm of the type SUBEXPRESSION.

Definition in file [pattern.c](#).

4.99.2 Macro Definition Documentation

4.99.2.1 PutInBuffers

```
#define PutInBuffers(
    pow )
```

Value:

```
AddRHS(AT.ebufnum,1); \
*out++ = SUBEXPRESSION; \
*out++ = SUBEXPSIZE; \
*out++ = C->numrhs; \
*out++ = pow; \
*out++ = AT.ebufnum; \
FILLSUB(out) \
r = AT.pWorkSpace[rhs+i]; \
if ( *r > 0 ) { \
    oldinr = r[*r]; r[*r] = 0; \
    AddNtoC(AT.ebufnum, (*r+1-ARGHEAD), (r+ARGHEAD), 14); \
    r[*r] = oldinr; \
} \
else { \
    ToGeneral(r,buffer,1); \
    buffer[buffer[0]] = 0; \
    AddNtoC(AT.ebufnum,buffer[0]+1,buffer,15); \
}
```

4.99.3 Function Documentation

4.99.3.1 TestMatch()

```
int TestMatch (
    PHEAD WORD * term,
    WORD * level )
```

This routine governs the pattern matching. If it decides that a substitution should be made, this can be either the insertion of a right hand side (C->rhs) or the automatic generation of terms as a result of an operation (like trace). The object to be replaced is removed from term and a subexpression pointer is inserted. If the substitution is made more than once there can be more subexpression pointers. Its number is positive as it corresponds to the level at which the C->rhs can be found in the compiler output. The subexpression pointer contains the wildcard substitution information. The power is found in *AT.TMout. For operations the subexpression pointer is negative and corresponds to an address in the array AT.TMout. In this array are then the instructions for the routine to be called and its number in the array 'Operations' The format is here: length,functionnumber,length-2 parameters

There is a certain complexity wrt repeat levels. Another complication is the poking of the wildcard values in the subexpression prototype in the compiler buffer. This was how things were done in the past with sequential FORM, but with the advent of TFORM this cannot be maintained. Now, for TFORM we make a copy of it. 7-may-2008 (JV): We cannot yet guarantee that this has been done 100% correctly. There are errors that occur in TFORM only and that may indicate problems.

```

```

00050
00051     There are several rules governing the allowable replacements.
00052     1: Multi with anything but symbols or dotproducts reverts
00053         to many.
00054     2: Each symbol can have only one (wildcard) power, so
00055         x^2*x^n? is illegal.
00056     3: when a single vector is used it replaces all occurrences
00057         of the vector. Therefore q*q(mu) or q*q(mu) cannot occur.
00058         Also q*q cannot be done.
00059     4: Loose vector elements are replaced with p(mu), dotproducts
00060         with p?.q.
00061     5: p?.q? is allowed.
00062     6: x^n? can revert to n = 0 if there is no power of x.
00063     7: x?^n? must match some x. There could be an ambiguity otherwise.

01968     #[ SubsInAll :      void SubsInAll()
01969
01970     This routine takes a match in id,all and stores it away in
01971     the AT.allbufnum 'compiler' buffer, after taking out the pattern.
01972     The main problem here is that id,all usually has (lots of) wildcards
01973     and their assignments are on stack and the difficult ones are in
01974     AT.ebufnum. Popping the stack while looking for more matches would
01975     loose those. Hence we have to copy them into yet another compiler
01976     buffer: AT.aebufnum. Because this may involve many matches and
01977     because the original term has only a limited number of arguments,
01978     it will pay to look for already existing ones in this buffer.
01979     (to be done later).

Include dependency graph for polygcd.cc:

Data Structures

- struct [BracketInfo](#)

Functions

- bool [gcd_heuristic_possible](#) (const [poly](#) &a)
- const [poly](#) [gcd_linear_helper](#) (const [poly](#) &a, const [poly](#) &b)

4.106.1 Detailed Description

Contains the routines for calculating greatest commons divisors of multivariate polynomials

Definition in file [polygcd.cc](#).

4.106.2 Function Documentation

4.106.2.1 gcd_heuristic_possible()

```
bool gcd_heuristic_possible (
    const poly & a )
```

Heuristic greatest common divisor of multivariate polynomials

4.106.3 Description

Checks whether the heuristic seems possible by estimating

$\text{MAX_}\{\text{terms}\} \{ \text{coeff} \wedge \text{PROD}_{\{i=1..\#\text{vars}\}} (\text{pow}_i+1) \}$

and comparing this with GCD_HEURISTIC_MAX_DIGITS.

4.106.4 Notes

- For small polynomials, this consumes time and never triggers.

Definition at line 1142 of file [polygcd.cc](#).

4.106.4.1 gcd_linear_helper()

```
const poly gcd_linear_helper (
    const poly & a,
    const poly & b )
```

4.109.1 Detailed Description

Contains methods to call the polynomial methods (written in C++) from the rest of Form (written in C). These include polynomial gcd computation, factorization and polyratfuns.

Definition in file [polywrap.cc](#).

4.109.2 Function Documentation

4.109.2.1 `poly_determine_modulus()`

```
WORD poly_determine_modulus (
    PHEAD bool multi_error,
    bool is_fun_arg,
    string message )
```

Modulus for polynomial algebra

4.109.3 Description

This method determines whether polynomial algebra is done with a modulus or not. This depends on AC.ncmod. If only_funargs is set it also depends on (AC.modmode & ALSOFUNARGS).

The program terminates if the feature is not implemented. Polynomial algebra modulo $M > \text{WORDSIZE}$ is not implemented. If multi_error is set, multivariate algebra mod M is not implemented.

4.109.4 Notes

- If AC.ncmod>0 and only_funargs=true and AC.modmode&ALSOFUNARGS=false, AN.ncmod is set to zero, for otherwise RaisPow calculates mod M .

Definition at line 79 of file [polywrap.cc](#).

Referenced by [poly_factorize\(\)](#), [poly_factorize_expression\(\)](#), [poly_gcd\(\)](#), [poly_ratfun_add\(\)](#), and [poly_ratfun_normalize\(\)](#).

4.109.4.1 `poly_gcd()`

```
WORD * poly_gcd (
    PHEAD WORD * a,
    WORD * b,
    WORD fit )
```

Polynomial gcd

4.109.5 Description

This method calculates the greatest common divisor of two polynomials, given by two zero-terminated Form-style term lists.

4.109.6 Notes

- The result is written at newly allocated memory
- Called from [ratio.c](#)
- Calls `polygcd::gcd`

Definition at line [124](#) of file [polywrap.cc](#).

References [poly_determine_modulus\(\)](#).

Here is the call graph for this function:

4.109.6.1 poly_divmod()

```
WORD * poly_divmod (  
    PHEAD WORD * a,  
    WORD * b,  
    int divmod,  
    WORD fit )
```

Definition at line [203](#) of file [polywrap.cc](#).

4.109.6.2 poly_div()

```
WORD * poly_div (  
    PHEAD WORD * a,  
    WORD * b,  
    WORD fit )
```

Definition at line [435](#) of file [polywrap.cc](#).

4.109.6.3 poly_rem()

```
WORD * poly_rem (  
    PHEAD WORD * a,  
    WORD * b,  
    WORD fit )
```

Definition at line [463](#) of file [polywrap.cc](#).

4.109.6.4 poly_ratfun_read()

```
void poly_ratfun_read (
    WORD * a,
    poly & num,
    poly & den )
```

Read a PolyRatFun

4.109.7 Description

This method reads a polyratfun starting at the pointer a. The resulting numerator and denominator are written in num and den. If MUSTCLEANPRF, the result is normalized.

4.109.8 Notes

- Calls polygcd::gcd

Definition at line 496 of file [polywrap.cc](#).

Referenced by [poly_ratfun_add\(\)](#), and [poly_ratfun_normalize\(\)](#).

4.109.8.1 poly_sort()

```
void poly_sort (
    PHEAD WORD * a )
```

Sort the polynomial terms

4.109.9 Description

Sorts the terms of a polynomial in Form [poly\(rat\)](#)fun order, i.e. lexicographical order with highest degree first.

4.109.10 Notes

- Uses Form sort routines with custom compare

Definition at line 590 of file [polywrap.cc](#).

References [Compare1\(\)](#), [CompareSymbols\(\)](#), [EndSort\(\)](#), [LowerSortLevel\(\)](#), [NewSort\(\)](#), [StoreTerm\(\)](#), and [SymbolNormalize\(\)](#).

Referenced by [poly_ratfun_add\(\)](#), and [poly_ratfun_normalize\(\)](#).

Here is the call graph for this function:

4.109.10.1 poly_ratfun_add()

```
WORD * poly_ratfun_add (
    PHEAD WORD * t1,
    WORD * t2 )
```

Addition of PolyRatFuns

4.109.11 Description

This method gets two pointers to polyratfuns with up to two arguments each and calculates the sum.

4.109.14 Notes

- The result overwrites the original term
- Called from [proces.c](#)
- Calls `poly::operators` and `polygcd::gcd`

Definition at line 769 of file [polywrap.cc](#).

References [poly_determine_modulus\(\)](#), [poly_ratfun_read\(\)](#), and [poly_sort\(\)](#).

Referenced by [PolyFunMul\(\)](#), and [PrepPoly\(\)](#).

Here is the call graph for this function:

4.109.14.1 poly_fix_minus_signs()

```
void poly_fix_minus_signs (
    factorized_poly & a )
```

Definition at line 921 of file [polywrap.cc](#).

4.109.14.2 poly_factorize()

```
WORD * poly_factorize (
    PHEAD WORD * argin,
    WORD * argout,
    bool with_arghead,
    bool is_fun_arg )
```

Factorization of function arguments / dollars

4.109.15 Description

This method factorizes a Form style argument or zero-terminated term list.

4.109.16 Notes

- Called from `poly_factorize_{argument,dollar}`
- Calls `polyfact::factorize`

Definition at line 986 of file `polywrap.cc`.

References `poly_determine_modulus()`.

Referenced by `poly_factorize_argument()`, and `poly_factorize_dollar()`.

Here is the call graph for this function:

4.109.16.1 poly_factorize_argument()

```
int poly_factorize_argument (
    PHEAD WORD * argin,
    WORD * argout )
```

Factorization of function arguments

4.109.17 Description

This method factorizes the Form-style argument `argin`.

4.109.18 Notes

- The result is written at argout
- Called from [argument.c](#)
- Calls `poly_factorize`

Definition at line 1112 of file [polywrap.cc](#).

References [poly_factorize\(\)](#).

Here is the call graph for this function:

4.109.18.1 poly_factorize_dollar()

```
WORD * poly_factorize_dollar (
    PHEAD WORD * argin )
```

Factorization of dollar variables

4.109.19 Description

This method factorizes a dollar variable.

4.109.20 Notes

- The result is written at newly allocated memory.
- Called from [dollar.c](#)
- Calls `poly_factorize`

Definition at line 1146 of file [polywrap.cc](#).

References [poly_factorize\(\)](#).

Here is the call graph for this function:

4.109.22.1 poly_unfactorize_expression()

```
int poly_unfactorize_expression (
    EXPRESSIONS expr )
```

Unfactorization of expressions

4.109.23 Description

This method expands a factorized expression.

4.109.24 Notes

- The result overwrites the input expression
- Called from [proces.c](#)

Definition at line 1535 of file [polywrap.cc](#).

References [EndSort\(\)](#), [Generator\(\)](#), [FiLe::handle](#), [LowerSortLevel\(\)](#), and [NewSort\(\)](#).

4.111.1 Detailed Description

Contains definitions for signals used/intercepted in FORM.

Some systems (especially LINUX) have not enough signals available so some of the (!documented!) signals are not defined. This file contains the definition of all signals used in the program. If the signal is not defined we define it as unused ($>NSIG$).

The include of signal.h must be first, before we try to define undefined signals.

Definition in file [portsignals.h](#).

4.113.1 Detailed Description

This is the preprocessor and all its routines.

Definition in file [pre.c](#).

4.113.2 Macro Definition Documentation

4.113.2.1 STRINGIFY

```
#define STRINGIFY(  
    x ) STRINGIFY__(x)
```

Definition at line 4329 of file [pre.c](#).

4.113.2.2 STRINGIFY__

```
#define STRINGIFY__(  
    x ) #x
```

Definition at line 4330 of file [pre.c](#).

4.113.2.3 SKIPBUFSIZE

```
#define SKIPBUFSIZE 20
```

Definition at line 4453 of file [pre.c](#).

4.113.2.4 KILL

```
#define KILL "kill"
```

Definition at line 5673 of file [pre.c](#).

4.113.2.5 KILLALL

```
#define KILLALL "killall"
```

Definition at line 5674 of file [pre.c](#).

4.113.2.6 DAEMON

```
#define DAEMON "daemon"
```

Definition at line 5675 of file [pre.c](#).

4.113.2.7 SHELL

```
#define SHELL "shell"
```

Definition at line 5676 of file [pre.c](#).

4.113.2.8 STDERR

```
#define STDERR "stderr"
```

Definition at line 5677 of file [pre.c](#).

4.113.2.9 TRUE_EXPR

```
#define TRUE_EXPR "true"
```

Definition at line 5679 of file [pre.c](#).

4.113.2.10 FALSE_EXPR

```
#define FALSE_EXPR "false"
```

Definition at line 5680 of file [pre.c](#).

4.113.2.11 NOSHELL

```
#define NOSHELL "noshell"
```

Definition at line 5681 of file [pre.c](#).

4.113.2.12 TERMINAL

```
#define TERMINAL "terminal"
```

Definition at line 5682 of file [pre.c](#).

4.113.3 Function Documentation

4.113.3.1 GetInput()

```
UBYTE GetInput (  
    void )
```

Definition at line 138 of file [pre.c](#).

4.113.3.2 ClearPushback()

```
void ClearPushback (  
    void )
```

Definition at line 167 of file [pre.c](#).

4.113.3.3 GetChar()

```
UBYTE GetChar (
    int level )
```

Definition at line 185 of file [pre.c](#).

4.113.3.4 CharOut()

```
void CharOut (
    UBYTE c )
```

Definition at line 495 of file [pre.c](#).

4.113.3.5 UnsetAllowDelay()

```
void UnsetAllowDelay (
    void )
```

Definition at line 516 of file [pre.c](#).

4.113.3.6 GetPreVar()

```
UBYTE * GetPreVar (
    UBYTE * name,
    int flag )
```

Definition at line 542 of file [pre.c](#).

4.113.3.7 PutPreVar()

```
int PutPreVar (
    UBYTE * name,
    UBYTE * value,
    UBYTE * args,
    int mode )
```

Inserts/Updates a preprocessor variable in the name administration.

Parameters

<i>name</i>	Character string with the variable name.
<i>value</i>	Character string with a possible value. Special case: if this argument is zero, then we have no value. Note: This is different from having an empty argument! This should only occur when the name starts with a ?
<i>args</i>	Character string with possible arguments.
<i>mode</i>	=0: always create a new name entry, =1: try to do a redefinition if possible.

Returns

Index of used entry in name list.

Definition at line 724 of file [pre.c](#).

Referenced by [ClearOptimize\(\)](#), [Generator\(\)](#), [Optimize\(\)](#), [PF_BroadcastRedefinedPreVars\(\)](#), [StartVariables\(\)](#), and [TheDefine\(\)](#).

4.113.3.8 PopPreVars()

```
void PopPreVars (
    int tonumber )
```

Definition at line 826 of file [pre.c](#).

4.113.3.9 IniModule()

```
void IniModule (
    int type )
```

Definition at line 841 of file [pre.c](#).

4.113.3.10 IniSpecialModule()

```
void IniSpecialModule (
    int type )
```

Definition at line 943 of file [pre.c](#).

4.113.3.11 PreProcessor()

```
void PreProcessor (
    void )
```

Definition at line 953 of file [pre.c](#).

4.113.3.12 PreProInstruction()

```
int PreProInstruction (
    void )
```

Definition at line 1172 of file [pre.c](#).

4.113.3.13 LoadInstruction()

```
int LoadInstruction (
    int mode )
```

Definition at line 1260 of file [pre.c](#).

4.113.3.14 LoadStatement()

```
int LoadStatement (
    int type )
```

Definition at line 1463 of file [pre.c](#).

4.113.3.15 ExpandTripleDots()

```
int ExpandTripleDots (
    int par )
```

Definition at line 1601 of file [pre.c](#).

4.113.3.16 FindKeyWord()

```
KEYWORD * FindKeyWord (
    UBYTE * theword,
    KEYWORD * table,
    int size )
```

Definition at line 1969 of file [pre.c](#).

4.113.3.17 FindInKeyWord()

```
KEYWORD * FindInKeyWord (
    UBYTE * theword,
    KEYWORD * table,
    int size )
```

Definition at line 2000 of file [pre.c](#).

4.113.3.18 TheDefine()

```
int TheDefine (
    UBYTE * s,
    int mode )
```

Preprocessor assignment. Possible arguments and values are treated and the new preprocessor variable is put into the name administration.

Parameters

<i>s</i>	Pointer to the character string following the preprocessor command.
<i>mode</i>	Bitmask. 0-bit clear: always create a new name entry, 0-bit set: try to redefine an existing name, 1-bit set: ignore preprocessor if/switch status.

Returns

zero: no errors, negative number: errors.

Definition at line 2030 of file [pre.c](#).

References [PutPreVar\(\)](#).

Here is the call graph for this function:

**4.113.3.19 DoCommentChar()**

```
int DoCommentChar (  
    UBYTE * s )
```

Definition at line 2103 of file [pre.c](#).

4.113.3.20 DoPreAssign()

```
int DoPreAssign (  
    UBYTE * s )
```

Definition at line 2134 of file [pre.c](#).

4.113.3.21 DoDefine()

```
int DoDefine (  
    UBYTE * s )
```

Definition at line 2165 of file [pre.c](#).

4.113.3.22 DoRedefine()

```
int DoRedefine (  
    UBYTE * s )
```

Definition at line 2175 of file [pre.c](#).

4.113.3.23 ClearMacro()

```
int ClearMacro (
    UBYTE * name )
```

Definition at line 2187 of file [pre.c](#).

4.113.3.24 TheUndefine()

```
int TheUndefine (
    UBYTE * name )
```

Definition at line 2215 of file [pre.c](#).

```
int DoUndefine (
    UBYTE * s )
```

Definition at line 2269 of file [pre.c](#).

4.113.3.26 DoInclude()

```
int DoInclude (
    UBYTE * s )
```

Definition at line 2321 of file [pre.c](#).

4.113.3.27 DoReverseInclude()

```
int DoReverseInclude (
    UBYTE * s )
```

Definition at line 2328 of file [pre.c](#).

4.113.3.28 Include()

```
int Include (
    UBYTE * s,
    int type )
```

Definition at line 2335 of file [pre.c](#).

4.113.3.29 DoPreExchange()

```
int DoPreExchange (
    UBYTE * s )
```

Definition at line 2496 of file [pre.c](#).

4.113.3.30 DoCall()

```
int DoCall (
    UBYTE * s )
```

Definition at line 2557 of file [pre.c](#).

4.113.3.31 DoDebug()

```
int DoDebug (
    UBYTE * s )
```

Definition at line 2729 of file [pre.c](#).

4.113.3.32 DoTerminate()

```
int DoTerminate (
    UBYTE * s )
```

Definition at line 2766 of file [pre.c](#).

4.113.3.33 DoContinueDo()

```
int DoContinueDo (
    UBYTE * s )
```

Jumps forward to the corresponding `#enddo` of the specified number of outer `#do` loops.

Syntax:

```
#continuedo [<number>=1]
```

If `number` is omitted, it defaults to 1. If `number` is zero then the instruction has no effect.

Definition at line 2800 of file [pre.c](#).

4.113.3.34 DoDo()

```
int DoDo (
    UBYTE * s )
```

Definition at line 2864 of file [pre.c](#).

4.113.3.35 DoBreakDo()

```
int DoBreakDo (
    UBYTE * s )
```

Definition at line 3079 of file [pre.c](#).

4.113.3.36 DoElse()

```
int DoElse (
    UBYTE * s )
```

Definition at line 3157 of file [pre.c](#).

07557     #[ DoUse :
07558
07559     Routine makes (inside the confines of the current namespace)
07560     a list of variables that are excluded from the namespace.
07561     Once the namespace is ended, the list is removed.
07562     The list can include names of variables, dollars and procedures.
07563     Preprocessor variables are excluded from the namespace. Their
07564     inclusion would be too complicated for the input streams.
07565     Note that the preprocessor variables that are arguments in a #do
07566     or in a procedure are on a stack and should not cause problems.
07567     Names of variables can be just that.
07568     Names of $-variables are also straightforward.
07569     Names of procedures should be preceded by a # character.
07570     Names of files (like in #include) should be enclosed by <>.
07571     The names are stored in a balanced tree. Each namespace may have
07572     its own tree. The toplevel (no namespace) does not allow a #use.

4.115.1 Detailed Description

Contains the central terms processor routines. This is the core of the virtual machine. All other files are to help these routines.

Definition in file [proces.c](#).

4.115.2 Macro Definition Documentation

4.115.2.1 DONE

```
#define DONE(
    x ) { retvalue = x; goto Done; }
```

TestSub hunts for subexpression pointers. If one is found its power is given in AN.TeSuOut. and the returnvalue is 'expressionnumber'. If the expression number is negative it is an expression on disk.

In addition this routine tries to locate subexpression pointers in functions. It also notices that action must be taken with any of the special functions.

Parameters

<i>term</i>	The term in which TestSub hunts for potential action
<i>level</i>	The number of the 'level' in the compiler buffer.

Returns

The number of the (sub)expression that was encountered.

Other values that are returned are in AN.TeSuOut, AR.TePos, AT.TMbuff, AN.TelFun, AN.Frozen, AT.TMaddr

The level in the compiler buffer is more or less the number of the statement in the module. Hence it refers to the element in the lhs array.

This routine is one of the most important routines in FORM.

Definition at line [683](#) of file [proces.c](#).

4.115.3 Function Documentation

4.115.3.1 Processor()

```
int Processor (
    void )
```

This is the central processor. It accepts a stream of Expressions which is accessed by calls to GetTerm. The expressions reside either in AR.infile or AR.hidefile The definitions of an expression are seen as an id-statement, so the primary Expressions should be written to the system of scratch files as single terms with an expression pointer. Each expression is terminated with a zero and the whole is terminated by two zeroes.

The routine DoExecute should determine whether results are to be printed, should revert the scratch I/O directions etc. In principle it is DoExecute that calls Processor.

Returns

if everything OK: 0. Otherwise error. The preprocessor may continue with compilation though. Really fatal errors should return on the spot by calling `Terminate`.

Definition at line 64 of file `proces.c`.

Here is the call graph for this function:

4.115.3.2 TestSub()

```
WORD TestSub (
    PHEAD WORD * term,
    WORD level )
```

Definition at line 685 of file `proces.c`.

4.115.3.3 InFunction()

```
int InFunction (
    PHEAD WORD * term,
    WORD * termout )
```

Makes the replacement of the subexpression with the number 'replac' in a function argument. Additional information is passed in some of the AR, AN, AT variables.

Parameters

<i>term</i>	The input term
<i>termout</i>	The output term

Returns

0: everything is fine, Negative: fatal, Positive: error.

Special attention should be given to nested functions!

Definition at line 2158 of file [proces.c](#).

References [Compare1\(\)](#), [CompareSymbols\(\)](#), [EndSort\(\)](#), [Generator\(\)](#), [LowerSortLevel\(\)](#), [NewSort\(\)](#), [StoreTerm\(\)](#), and [SymbolNormalize\(\)](#).

Referenced by [Generator\(\)](#).

Here is the call graph for this function:

4.115.3.4 InsertTerm()

```

int InsertTerm (
    PHEAD WORD * term,
    WORD replac,
    WORD extractbuff,
    WORD * position,

```

```
WORD * termout,  
WORD tepos )
```

Puts the terms 'term' and 'position' together into a single legal term in termout. replac is the number of the subexpression that should be replaced. It must be a positive term. When action is needed in the argument of a function all terms in that argument are dealt with recursively. The subexpression is sorted. Only one subexpression is done at a time this way.

Parameters

<i>term</i>	the input term
<i>replac</i>	number of the subexpression pointer to replace
<i>extractbuff</i>	number of the compiler buffer <i>replac</i> refers to
<i>position</i>	position from where to take the term in the compiler buffer
<i>termout</i>	the output term
<i>tepos</i>	offset in term where the subexpression is.

Returns

Normal conventions (OK = 0).

Definition at line 2728 of file [proces.c](#).

Referenced by [Deferred\(\)](#), [Generator\(\)](#), and [PF_Deferred\(\)](#).

4.115.3.5 PasteFile()

```

LONG PasteFile (
    PHEAD WORD number,
    WORD * accum,
    POSITION * position,
    WORD ** accfill,
    RENUMBER renumber,
    WORD * freeze,
    WORD nexpr )

```

Gets a term from stored expression *expr* and puts it in the accumulator at position *number*. It returns the length of the term that came from file.

Parameters

<i>number</i>	number of partial terms to skip in <i>accum</i>
<i>accum</i>	the accumulator
<i>position</i>	file position from where to get the stored term
<i>accfill</i>	returns tail position in <i>accum</i>
<i>renumber</i>	the renumber struct for the variables in the stored expression
<i>freeze</i>	information about if we need only the contents of a bracket
<i>nexpr</i>	the number of the stored expression

Returns

Normal conventions (OK = 0).

Definition at line 2864 of file [proces.c](#).

Referenced by [Generator\(\)](#).

4.115.3.6 PasteTerm()

```
WORD * PasteTerm (
    PHEAD WORD number,
    WORD * accum,
    WORD * position,
    WORD times,
    WORD divby )
```

Puts the term at position in the accumulator *accum* at position '*number*+1'. if *times* > 0 the coefficient of this term is multiplied by *times*/*divby*.

Parameters

<i>number</i>	The number of term fragments in <i>accum</i> that should be skipped
<i>accum</i>	The accumulator of term fragments
<i>position</i>	A position in (typically) a compiler buffer from where a (piece of a) term comes.
<i>times</i>	Multiply the result by this
<i>divby</i>	Divide the result by this.

This routine is typically used when we have to replace a (sub)expression pointer by a power of a (sub)expression. This uses mostly a binomial expansion and the new term is the old term multiplied one by one by terms of the new expression. The factors *times* and *divby* keep track of the binomial coefficient. Once this is complete, the routine *FiniTerm* will make the contents of the accumulator into a proper term that still needs to be normalized.

Definition at line [2986](#) of file [proces.c](#).

Referenced by [Generator\(\)](#).

4.115.3.7 FiniTerm()

```
int FiniTerm (
    PHEAD WORD * term,
    WORD * accum,
    WORD * termout,
    WORD number,
    WORD tepos )
```

Concatenates the contents of the accumulator into a single legal term, which replaces the subexpression pointer

Parameters

<i>term</i>	the input term with the (sub)expression subterm
<i>accum</i>	the accumulator with the term fragments
<i>termout</i>	the location where the output should be written
<i>number</i>	the number of term fragments in the accumulator
<i>tepos</i>	the position of the subterm in term to be replaced

Definition at line [3051](#) of file [proces.c](#).

Referenced by [DoOnePow\(\)](#), and [Generator\(\)](#).

4.115.3.8 Generator()

```
int Generator (
    PHEAD WORD * term,
    WORD level )
```

The heart of the program. Here the expansion tree is set up in one giant recursion

Parameters

<i>term</i>	the input term. may be overwritten
<i>level</i>	the level in the compiler buffer (number of statement)

Returns

Normal conventions (OK = 0).

The routine looks first whether there are unsubstituted (sub)expressions. If so, one of them gets inserted term by term and the new term is used in a renewed call to Generator. If there are no (sub)expressions, the term is normalized, the compiler level is raised (next statement) and the program looks what type of statement this is. If this is a special statement it is either treated on the spot or the appropriate routine is called. If it is a substitution, the pattern matcher is called (TestMatch) which tells whether there was a match. If so we need to call TestSub again to test for (sub)expressions. If we run out of levels, the term receives a final treatment for modulus calculus and/or brackets and is then sent off to the sorting routines.

Definition at line 3250 of file [proces.c](#).

Here is the call graph for this function:

4.115.3.9 DoOnePow()

```
int DoOnePow (
    PHEAD WORD * term,
    WORD power,
    WORD nex,
    WORD * accum,
    WORD * aa,
    WORD level,
    WORD * freeze )
```

Routine gets one power of an expression in the scratch system. If there are more powers needed there will be a recursion.

No attempt is made to use binomials because we have no information about commuting properties.

There is a searching for the contents of brackets if needed. This searching may be rather slow because of the single links.

Parameters

<i>term</i>	is the term we are adding to.
<i>power</i>	is the power of the expression that we need.
<i>nex</i>	is the number of the expression.
<i>accum</i>	is the accumulator of terms. It accepts the termfragments that are made into a proper term in FiniTerm

Parameters

<i>aa</i>	points to the start of the entire accumulator. In *aa we store the number of term fragments that are in the accumulator.
<i>level</i>	is the current depth in the tree of statements. It is needed to continue to the next operation/substitution with each generated term
<i>freeze</i>	is the pointer to the bracket information that should be matched.

Referenced by [DoOnePow\(\)](#), and [Generator\(\)](#).

Here is the call graph for this function:

4.115.3.10 Deferred()

```

int Deferred (
    PHEAD WORD * term,
    WORD level )

```

Picks up the deferred brackets. These are the bracket contents of which we postpone the reading when we use the 'Keep Brackets' statement. These contents are multiplying the terms just before they are sent to the sorting system. Special attention goes to having it thread-safe We have to lock positioning the file and reading it in a thread specific buffer.

Parameters

<i>term</i>	The term that must be multiplied by the contents of the current bracket
<i>level</i>	The compiler level. This is needed because after multiplying term by term we call Generator again.

Definition at line 4838 of file [proces.c](#).

References [Generator\(\)](#), and [InsertTerm\(\)](#).

Referenced by [Generator\(\)](#).

Here is the call graph for this function:

4.115.3.11 PrepPoly()

```

int PrepPoly (
    PHEAD WORD * term,
    WORD par )

```

Routine checks whether the count of function AR.PolyFun is zero or one. If it is one and it has one scalarlike argument the coefficient of the term is pulled inside the argument. If the count is zero a new function is made with the coefficient as its only argument. The function should be placed at its proper position.

When this function is active it places the PolyFun as last object before the coefficient. This is needed because otherwise the compress algorithm has problems in MergePatches.

The bracket routine should also place the PolyFun at a comparable spot. The compression should then stop at the PolyFun. It doesn't really have to stop when writing the final result but this may be too complicated.

The parameter `par` tells whether we are at groundlevel or inside a function or dollar variable.

Definition at line 4966 of file [proces.c](#).

References [poly_ratfun_normalize\(\)](#).

Referenced by [Generator\(\)](#).

Here is the call graph for this function:

4.115.3.12 PolyFunMul()

```
int PolyFunMul (
    PHEAD WORD * term )
```

Multiplies the arguments of multiple occurrences of the polyfun. In this routine we do the original PolyFun with one argument only. The PolyRatFun (PolyFunType = 2) is done in a dedicated routine in the file [polywrap.cc](#). The new result is written over the old result.

Parameters

<i>term</i>	It contains the input term and later the output.
-------------	--

Returns

Normal conventions (OK = 0).

Definition at line 5354 of file [proces.c](#).

References [EndSort\(\)](#), [LowerSortLevel\(\)](#), [NewSort\(\)](#), [poly_ratfun_normalize\(\)](#), and [StoreTerm\(\)](#).

4.117.1 Detailed Description

A variety of routines: The ratio command for partial fractioning (rather old. Schoonschip inheritance) The sum routines.

Definition in file [ratio.c](#).

4.117.2 Function Documentation

4.117.2.1 RatioFind()

```
int RatioFind (
    PHEAD WORD * term,
    WORD * params )
```

Definition at line 62 of file [ratio.c](#).

4.117.2.2 RatioGen()

```
int RatioGen (
    PHEAD WORD * term,
    WORD * params,
    WORD num,
    WORD level )
```

Definition at line 170 of file [ratio.c](#).

4.117.2.3 BinomGen()

```
int BinomGen (
    PHEAD WORD * term,
    WORD level,
    WORD ** tstops,
    WORD x1,
    WORD x2,
    WORD pow1,
    WORD pow2,
    WORD sign,
    UWORD * coef,
    WORD ncoef )
```

Definition at line 320 of file [ratio.c](#).

4.117.2.4 DoSumF1()

```
int DoSumF1 (
    PHEAD WORD * term,
    WORD * params,
    WORD replac,
    WORD level )
```

Definition at line 395 of file [ratio.c](#).

4.117.2.5 Glue()

```
int Glue (
    PHEAD WORD * term1,
    WORD * term2,
    WORD * sub,
    WORD insert )
```

Definition at line 461 of file [ratio.c](#).

4.117.2.6 DoSumF2()

```
int DoSumF2 (
    PHEAD WORD * term,
    WORD * params,
    WORD replac,
    WORD level )
```

Definition at line 520 of file [ratio.c](#).

4.117.2.7 GCDfunction()

```
int GCDfunction (
    PHEAD WORD * term,
    WORD level )
```

Definition at line 609 of file [ratio.c](#).

4.117.2.8 GCDfunction3()

```
WORD * GCDfunction3 (
    PHEAD WORD * in1,
    WORD * in2 )
```

Definition at line 1141 of file [ratio.c](#).

4.117.2.9 PutExtraSymbols()

```
WORD * PutExtraSymbols (
    PHEAD WORD * in,
    WORD startebuf,
    int * actionflag )
```

Definition at line 1244 of file [ratio.c](#).

4.117.2.10 TakeExtraSymbols()

```
WORD * TakeExtraSymbols (
    PHEAD WORD * in,
    WORD startebuf )
```

Definition at line 1273 of file [ratio.c](#).

4.117.2.11 MultiplyWithTerm()

```
WORD * MultiplyWithTerm (
    PHEAD WORD * in,
    WORD * term,
    WORD par )
```

Definition at line 1312 of file [ratio.c](#).

4.117.2.12 TakeContent()

```
WORD * TakeContent (
    PHEAD WORD * in,
    WORD * term )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. Here the input is a sequence of terms in 'in' and the answer is a content-free sequence of terms. This sequence has been allocated by the Malloc1 routine in a call to EndSort, unless the expression was already content-free. In that case the input pointer is returned. The content is returned in term. This is supposed to be a separate allocation, made by TermMalloc in the calling routine.

4.117.2.13 MergeSymbolLists()

```
int MergeSymbolLists (
    PHEAD WORD * old,
    WORD * extra,
    int par )
```

Definition at line 1808 of file [ratio.c](#).

4.117.2.14 MergeDotproductLists()

```
int MergeDotproductLists (
    PHEAD WORD * old,
    WORD * extra,
    int par )
```

Definition at line 1927 of file [ratio.c](#).

4.117.2.15 CreateExpression()

```
WORD * CreateExpression (
    PHEAD WORD nexp )
```

Definition at line 2020 of file [ratio.c](#).

4.117.2.16 GCDterms()

```
int GCDterms (
    PHEAD WORD * term1,
    WORD * term2,
    WORD * termout )
```

Definition at line 2076 of file [ratio.c](#).

4.117.2.17 ReadPolyRatFun()

```
int ReadPolyRatFun (
    PHEAD WORD * term )
```

Definition at line 2264 of file [ratio.c](#).

4.117.2.18 FromPolyRatFun()

```
int FromPolyRatFun (
    PHEAD WORD * fun,
    WORD ** numout,
    WORD ** denout )
```

Definition at line 2383 of file [ratio.c](#).

4.117.2.19 TakeSymbolContent()

```
WORD * TakeSymbolContent (
    PHEAD WORD * in,
    WORD * term )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. We allow only symbols as this code is used for the polyratfun only. We have a special routine, because the generic TakeContent does too much work and speed is at a premium here. Input: *in* is the input expression as a sequence of terms. **Output:** *term*: the content return value: the contentfree expression. it is in new allocation, made by TermMalloc. (should be in a TermMalloc space?)

```

```

00138 /*
00139      #] RatioFind :
00140      #[ RatioGen :
00141
00142      The algorithm:
00143      x1^-n1*x2^n2 ==> x2 --> x1 + x3
00144      x1^n1*x2^-n2 ==> x1 --> x2 - x3
00145      x1^-n1*x2^-n2 ==>
00146
00147          +sum(i=0,n1-1){(-1)^i*binom(n2-1+i,n2-1)
00148              *x3^-(n2+i)*x1^-(n1-i)}
00149          +sum(i=0,n2-1){(-1)^(n1)*binom(n1-1+i,n1-1)
00150              *x3^-(n1+i)*x2^-(n2-i)}
00151
00152      Actually there is an amount of arbitrariness in the first two
00153      formulae and the replacement x2 -> x1 + x3 could be made 'by hand'.
00154      It is better to use the nontrivial 'minimal change' formula:
00155
00156      x1^-n1*x2^n2:   if ( n1 >= n2 ) {
00157                      +sum(i=0,n2){x3^i*x1^-(n1-n2+i)*binom(n2,i)}
00158                      }
00159                      else {
00160                          sum(i=0,n2-n1){x2^(n2-n1-i)*x3^i*binom(n1-1+i,n1-1)}
00161                          +sum(i=0,n1-1){x3^(n2-i)*x1^-(n1-i)*binom(n2,i)}
00162                      }
00163      x1^n1*x2^-n2:   Same but x3 -> -x3.
00164
00165      The contents of the AT.TMout/params array are:
00166      length,type,x1,x2,x3,n1,n2
00167
00168 */
00169

00376
00377     Routine expands a sum_ function.
00378     Its arguments are:
00379     The term in which the function occurs.
00380     The parameter list:
00381         length of parameter field
00382         function number (SUMNUM1)
00383         number of the symbol that is loop parameter
00384         min value
00385         max value
00386         increment
00387     the number of the subexpression to be removed
00388     the level in the generation tree.
00389
00390     Note that the insertion of the loop parameter in the argument
00391     is done via the regular wildcard substitution mechanism.

01122     #] GCDfunction :
01123     #[ GCDfunction3 :
01124
01125     Finds the GCD of the two arguments which are buffers with terms.
01126     In principle the first buffer can have only one term.
01127
01128     If both buffers have more than one term, we need to replace all
01129     non-symbolic objects by generated symbols and substitute that back
01130     afterwards. The rest we leave to the powerful routines.
01131     Philosophical problem: What do we do with GCD_(x/z+y,x+y*z) ?
01132
01133     Method:
01134     If we have only negative powers of z and no positive powers we let
01135     the EXTRASYMBOLS do their job. When mixed, multiply the arguments with
01136     the negative powers with enough powers of z to eliminate the negative powers.
01137     The DENOMINATOR function is always eliminated with the mechanism as we
01138     cannot tell whether there are positive powers of its contents.

4.119.1 Detailed Description

This file contains the numerical routines. The arithmetic in FORM is normally over the rational numbers. Hence there are routines for dealing with integers and with rational of 'arbitrary precision' (within limits) There are also routines for that calculus modulus an integer. In addition there are the routines for factorials and Bernoulli numbers. The random number function is currently only for internal purposes.

4.119.3.17 RaisPow()

```
int RaisPow (
    PHEAD UWORD * a,
    WORD * na,
    UWORD b )
```

Definition at line 1229 of file [reken.c](#).

4.119.3.18 RaisPowCached()

```
void RaisPowCached (
    PHEAD WORD x,
    WORD n,
    UWORD ** c,
    WORD * nc )
```

Computes power x^n and caches the value

4.119.4 Description

Calculates the power x^n and stores the results for caching purposes. The pointer c (i.e., the pointer, and not what it points to) is overwritten. What it points to should not be overwritten in the calling function.

4.119.5 Notes

- Caching is done in `AT.small_power[]`. This array is extended if necessary.

Definition at line 1297 of file [reken.c](#).

Referenced by [poly::divmod_heap\(\)](#), [poly::divmod_univar\(\)](#), and [poly::mul_heap\(\)](#).

4.119.5.1 RaisPowMod()

```
WORD RaisPowMod (
    WORD x,
    WORD n,
    WORD m )
```

Definition at line 1384 of file [reken.c](#).

4.119.5.2 NormalModulus()

```
int NormalModulus (
    UWORD * a,
    WORD * na )
```

Brings a modular representation in the range $-p/2$ to $+p/2$ The return value tells whether anything was done. Routine made in the general modulus revamp of July 2008 (JV).

Definition at line 1404 of file [reken.c](#).

Referenced by [AddCoef\(\)](#), and [MergePatches\(\)](#).

4.119.5.3 MakeInverses()

```
int MakeInverses (
    void )
```

Makes a table of inverses in modular calculus The modulus is in `AC.cmod` and `AC.ncmod` One should notice that the table of inverses can only be made if the modulus fits inside a single FORM word. Otherwise the table lookup becomes too difficult and the table too long.

Definition at line 1441 of file [reken.c](#).

References [GetModInverses\(\)](#).

Here is the call graph for this function:

4.119.5.4 GetModInverses()

```
int GetModInverses (
    WORD m1,
    WORD m2,
    WORD * im1,
    WORD * im2 )
```

Input m1 and m2, which are relative prime. determines $a*m1+b*m2 = 1$ (and 1 is the gcd of m1 and m2) then $a*m1 = 1 \bmod m2$ and hence $im1 = a$. and $b*m2 = 1 \bmod m1$ and hence $im2 = b$. Set $m1 = 0*m1+1*m2 = a1*m1+b1*m2$ $m2 = 1*m1+0*m2 = a2*m1+b2*m2$ If everything is OK, the return value is zero

02212 #else
02213 /*
02214 New routine for GcdLong that uses smart shortcuts.
02215 Algorithm by J. Vermaseren 15-nov-2006.
02216 It runs faster for very big numbers but only by a fixed factor.
02217 There is no improvement in the power behaviour.
02218 Improvement on the whole of hf9 (multiple zeta values at weight 9):
02219 Better than a factor 2 on a 32 bits architecture and 2.76 on a
02220 64 bits architecture.
02221 On hf10 (MZV's at weight 10), 64 bits architecture: factor 7.
02222
02223 If we have two long numbers (na,nb > GCDMAX) we will work in a
02224 truncated way. At the moment of writing (15-nov-2006) it isn't
02225 clear whether this algorithm is an invention or a reinvention.
02226 A short search on the web didn't show anything.
02227
02228 31-jul-2007:
02229 A better search shows that this is an adaptation of the Lehmer-Euclid
02230 algorithm, already described in Knuth. Here we can work without upper
02231 and lower limit because we are only interested in the GCD, not the
02232 extra numbers. Also it takes already some features of the double
02233 digit Lehmer-Euclid algorithm of Jeebelean it seems.
02234
02235 Maybe this can be programmed slightly better and we can get another
02236 few percent speed increase. Further improvements for the asymptotic
02237 case come from splitting the calculation as in Karatsuba and working
02238 with FFT divisions and multiplications etc. But this is when hundreds
02239 of words are involved at the least.
02240
02241 Algorithm
02242
02243 1: while ( na > nb || nb < GCDMAX ) {
02244     if ( nb == 0 ) { result in a }
02245     c = a % b;
02246     a = b;
02247     b = c;
02248 }
02249
02250 2: Make the truncated values in which a and b are the combinations
02251 of the top two words of a and b. The whole numbers are aa and bb now.
02252 3: ma1 = 1; ma2 = 0; mb1 = 0; mb2 = 1;
02253 4: A = a; B = b; m = a/b; c = a - m*b;
02254     c = ma1*a+ma2*b-m*(mb1*a+mb2*b) = (ma1-m*mb1)*a+(ma2-m*mb2)*b

```

```

02255     mc1 = ma1-m*mb1; mc2 = ma2-m*mb2;
02256 5: a = b; ma1 = mb1; ma2 = mb2;
02257   b = c; mb1 = mc1; mb2 = mc2;
02258 6: if ( b != 0 && nb >= FULLMAX ) goto 4;
02259 7: Now construct the new quantities
02260     ma1*aa+ma2*bb and mb1*aa+mb2*bb
02261 8: goto 1;
02262
02263 The essence of the above algorithm is that we do the divisions only
02264 on relatively short numbers. Also usually there are many steps 4&5
02265 for each step 7. This eliminates many operations.
02266 The termination at FULLMAX is that we make errors by not considering
02267 the tail of the number. If we run b down all the way, the errors combine
02268 in such a way that the new numbers may be of the same order as the old
02269 numbers. By stopping halfway we don't get the error beyond halfway
02270 either. Unfortunately this means that a >= FULLMAX and hence na > nb
02271 which means that next we will have a complete division. But just once.
02272 Running the steps 4-6 till a < FULLMAX runs already into problems.
02273 It may be necessary to experiment a bit to obtain the optimum value
02274 of GCDMAX.

02883     #] MakeRational:
02884     #[ MakeLongRational:
02885
02886     Converts the long number a mod m into the fraction b
02887     One of the properties of b is that num,den < sqrt(m)
02888     The algorithm: Start with:   m 0
02889                                a 1
02890     Make now c=m/a, c1=m/a      c c2=0-c1*1
02891     Make now d=a/c, d1=a/c      d d2=1-d1*c2
02892     Make now e=c/d, e1=c/d      e e2=1-e1*d2
02893     etc till in the first column we get a number < sqrt(m)
02894     We have then f,f2 and the fraction is f/f2.
02895     If at any moment we get a zero, m contained an unlucky prime.
02896
02897     Note that this can be made a lot faster when we make the same
02898     improvements as in the GCD routine. That is something for later.

00044      #[ Reshuf :
00045
00046      Routines to rearrange dummy indices, so that
00047      a: The notation becomes reasonably unique (the perfect job
00048         may consume very much time).
00049      b: The value of AR.CurDum is reset.
00050
00051      Also some routines are needed to aid in the reading of stored
00052      expressions. Also in those expressions there can be dummy
00053      indices, and there should be no conflict with the already
00054      existing dummies.
00055
00056      #[ ReNumber :
00057
00058      Reads the term, tests for dummies, and puts them in order.
00059      Note that this is kind of a first order approximation.
00060      There is quite some room to make this routine 'smart'
00061      First order:
00062          First index will be lowest, second will be next etc.
00063      Second order:
00064          Functions with more than one index and symmetry properties
00065          have some look ahead to see which index is the first to
00066          find its partner.
00067      Third order:
00068          Take the ordering of the functions into account.
00069      Fourth order:
00070          Try all permutations and see which one gives the 'minimal' term.
00071      Currently we use only the first order.
00072
00073      We need a scratch array for the numbers we find, and one for
00074      the addresses at which these numbers are.
00075      We can use the space for the Scrut arrays. There are 13 of those
00076      and each is AM.MaxTal UWORDS long.
00077

01171 /*
01172     t points at the distrib_ function to be expanded.
01173     fun1,fun2 and typ1,typ2 are the two functions and their types.
01174     ntype indicates the action:

```

```

01175      0:  Make all possible divisions:  2^nargs
01176      1:  fun1 should get n arguments:  nargs! / ( n! (nargs-n)! )
01177      2:  fun2 should get n arguments:  nargs! / ( n! (nargs-n)! )
01178  The distinction between 1 and two is for noncommuting objects.
01179      3:  fun1 should get n arguments. Super symmetric option.
01180      4:  fun2 idem
01181  The super symmetric option involves:
01182      a:  arguments get sorted
01183      b:  identical arguments are seen as such. Hence not all their
01184          distributions are taken into account. It is as if after the
01185          distrib there is a symmetrize fun1; symmetrize fun2;
01186      c:  Hence if the occurrence of each argument is a,b,c,...
01187          and their occurrence in fun1 is a1,b1,c1,... and in fun2
01188          is a2,b2,c2,... then each term is generated (a1+a2)!/a1!/a2!
01189          (b1+b2)!/b1!/b2! (c1+c2)!/c1!/c2! ... times.
01190      d:  We have to make an array of occurrences and positions.
01191      e:  Then we sort the arguments indirectly.
01192      f:  Next we generate the argument lists in the same way as we
01193          generate powers of expressions with binomials. Hence we need
01194          a third array to keep track of the 'powers'

01589
01590 Checks whether the function in tfun is a partitions_ function
01591 that can be expanded. If it can a number of relevant objects is
01592 inside the struct parti.
01593 This test is not entirely trivial because there are many restrictions
01594 w.r.t. the arguments.
01595 Syntax (still to be implemented)
01596 partitions_(number_of_partition_entries,[function,number,]^nope,arguments)
01597 [function,number,]: can be
01598     f,3     for a partition of 3 arguments
01599     f,0     for the remaining arguments (should be last)
01600     num1,f,num2 with num1 effectively a number of partitions but this
01601                counts as num1 entries.
01602     0,f,num2: all partitions have num2 arguments. No number of partition
01603                entries needed. If num2 does not divide the number of
01604                arguments there will be no action.
01605 */

01785     Now comes the part where we have to make sure that
01786     a: we generate all partitions.
01787     b: we generate only different partitions.
01788     c: we get the proper combinatorics factor.
01789     Method:
01790     Suppose the largest partition needs n objects and there are m partitions.
01791     We allocate m arrays of n 'digits'. Make in the smaller partitions the
01792     appropriate leading digits zero.
01793     Divide the largest numbers (of the arguments) over the partitions as
01794     leftmost digits (after possible zeroes). The arrays, seen as numbers,
01795     should be such that each is less or equal to its left neighbour. Take the
01796     next largest numbers, etc. This generates unique partitions and all of
01797     them. Because we have a formula for the multiplicity, this should do it.
01798

02196 #[ Shuffle :
02197
02198 How to make shuffles:
02199
02200 We have two lists of arguments. We have to make a single
02201 shuffle of them. All combinations. Doubles should have as
02202 much as possible a combinatorics factor. Sometimes this is
02203 very difficult as in:
02204 (0,1,2)x(0,1,3) = -> (0,1) is a repeated pattern and the
02205 factor on that is difficult
02206 Simple way: (without combinatorics)
02207 repeat id f0(?c)*f(x1?,?a)*f(x2?,?b) =
02208         +f0(?c,x1)*f(?a)*f(x2,?b)
02209         +f0(?c,x2)*f(x1,?a)*f(?b);
02210
02211 Refinement:
02212 if ( x1 == x2 ) check how many more there are of the same.
02213 --> (n1,x) and (n2,x)
02214 id f0(?c)*f1((n1,x),?b)*f2((n2,x),?c) =
02215         +binom_(n1+n2,n1)*f0(?c,(n1+n2,x))*f1(?a)*f2(?b)
02216         +sum_(j,0,n1-1,binom_(n2+j,j)*f0(?c,(j+n2,x))
02217             *f1((n1-j),?a)*f2(?b))*force2

```

```

02217             +sum_(j,0,n2-1,binom_(n1+j,j)*f0(?c,(j+n1,x))
02218                 *f1(?a)*f2((n2-j),?b))*force1
02219     The force operation can be executed directly
02220
02221     The next question is how to program this: recursively or linearly
02222     which would require simulation of a recursion. Recursive is clearest
02223     but we need to pass a number of arguments from the calling routine
02224     to the final routine. This is done with AN.SHvar.
02225
02226     We need space for the accumulation of the combinatoric factors.

02470 #] FinishShuffle :
02471 #[ DoStuffle :
02472
02473 Stuffling is a variation of shuffling.
02474 In the stuffling we insist that the arguments are (short) integers. nonzero.
02475 The stuffle sum is  $x \text{ st } y = \text{sig}_-(x) * \text{sig}_-(y) * (\text{abs}(x) + \text{abs}(y))$ 
02476 The way we do this is:
02477     1: count the arguments in each function: n1, n2

```

```

02478         2: take the minimum minval = min(n1,n2).
02479         3: for ( j = 0; j <= min; j++ ) take j elements in each of the lists.
02480         4: the j+1 groups of remaining arguments have to each be shuffled
02481         5: the j selected pairs have to be stuffle added.
02482         We can use many of the shuffle things.
02483         Considering the recursive nature of the generation we actually don't
02484         need to know n1, n2, minval.
02485     */

4.123.1 Detailed Description

Contains the functions that deal with the writing of expressions/terms in a textual representation. (Dutch schrijven = to write)

Definition in file [sch.c](#).

4.123.2 Function Documentation

4.123.2.1 StrCopy()

```
UBYTE * StrCopy (
    UBYTE * from,
    UBYTE * to )
```

Definition at line [49](#) of file [sch.c](#).

4.123.2.2 AddToLine()

```
void AddToLine (
    UBYTE * s )
```

Definition at line [64](#) of file [sch.c](#).

4.123.2.3 FiniLine()

```
void FiniLine (
    void )
```

Definition at line [164](#) of file [sch.c](#).

4.123.2.4 IniLine()

```
void IniLine (
    WORD extrablk )
```

Definition at line 249 of file [sch.c](#).

4.123.2.5 LongToLine()

```
void LongToLine (
    UWORD * a,
    WORD na )
```

Definition at line 285 of file [sch.c](#).

4.123.2.6 RatToLine()

```
void RatToLine (
    UWORD * a,
    WORD na )
```

Definition at line 319 of file [sch.c](#).

4.123.2.7 TalToLine()

```
void TalToLine (
    UWORD x )
```

Definition at line 504 of file [sch.c](#).

4.123.2.8 TokenToLine()

```
void TokenToLine (
    UBYTE * s )
```

Definition at line 533 of file [sch.c](#).

4.123.2.9 CodeToLine()

```
UBYTE * CodeToLine (
    WORD number,
    UBYTE * Out )
```

Definition at line 640 of file [sch.c](#).

4.123.2.10 MultiplyToLine()

```
void MultiplyToLine (
    void )
```

Definition at line 653 of file [sch.c](#).

4.123.2.11 AddArrayIndex()

```
UBYTE * AddArrayIndex (
    WORD num,
    UBYTE * out )
```

Definition at line 678 of file [sch.c](#).

4.123.2.12 PrtTerms()

```
void PrtTerms (
    void )
```

Definition at line 698 of file [sch.c](#).

4.123.2.13 WrtPower()

```
UBYTE * WrtPower (
    UBYTE * Out,
    WORD Power )
```

Definition at line 720 of file [sch.c](#).

4.123.2.14 PrintTime()

```
void PrintTime (
    UBYTE * mess )
```

Definition at line 766 of file [sch.c](#).

4.123.2.15 WriteLists()

```
void WriteLists (
    void )
```

Definition at line 792 of file [sch.c](#).

4.123.2.16 WriteDictionary()

```
void WriteDictionary (
    DICTIONARY * dict )
```

Definition at line 1289 of file [sch.c](#).

4.123.2.17 WriteArgument()

```
void WriteArgument (
    WORD * t )
```

Definition at line 1406 of file [sch.c](#).

4.123.2.18 WriteSubTerm()

```
int WriteSubTerm (
    WORD * sterm,
    WORD first )
```

Definition at line 1524 of file [sch.c](#).

4.123.2.19 WriteInnerTerm()

```
int WriteInnerTerm (
    WORD * term,
    WORD first )
```

Definition at line 1933 of file [sch.c](#).

4.123.2.20 WriteTerm()

```
int WriteTerm (
    WORD * term,
    WORD * lbrac,
    WORD first,
    WORD prtft,
    WORD br )
```

Definition at line 2133 of file [sch.c](#).

4.123.2.21 WriteExpression()

```
int WriteExpression (
    WORD * terms,
    LONG ltot )
```

Definition at line 2455 of file [sch.c](#).

4.123.2.22 WriteAll()

```
int WriteAll (
    void )
```

Definition at line 2486 of file [sch.c](#).

4.123.2.23 WriteOne()

```
int WriteOne (
    UBYTE * name,
    int alreadyinline,
    int nosemi,
    WORD plus )
```

Definition at line 2712 of file [sch.c](#).
